# Short Introduction To Course Authors

## ● Dr Heinz Kabutz

- Born in Cape Town, South Africa, now lives in Greece / Europe
- Created The Java Specialists' Newsletter
  - <http://www.javaspecialists.eu/archive/archive.html>
- One of the first Sun Java Champions
  - <https://java-champions.dev.java.net>

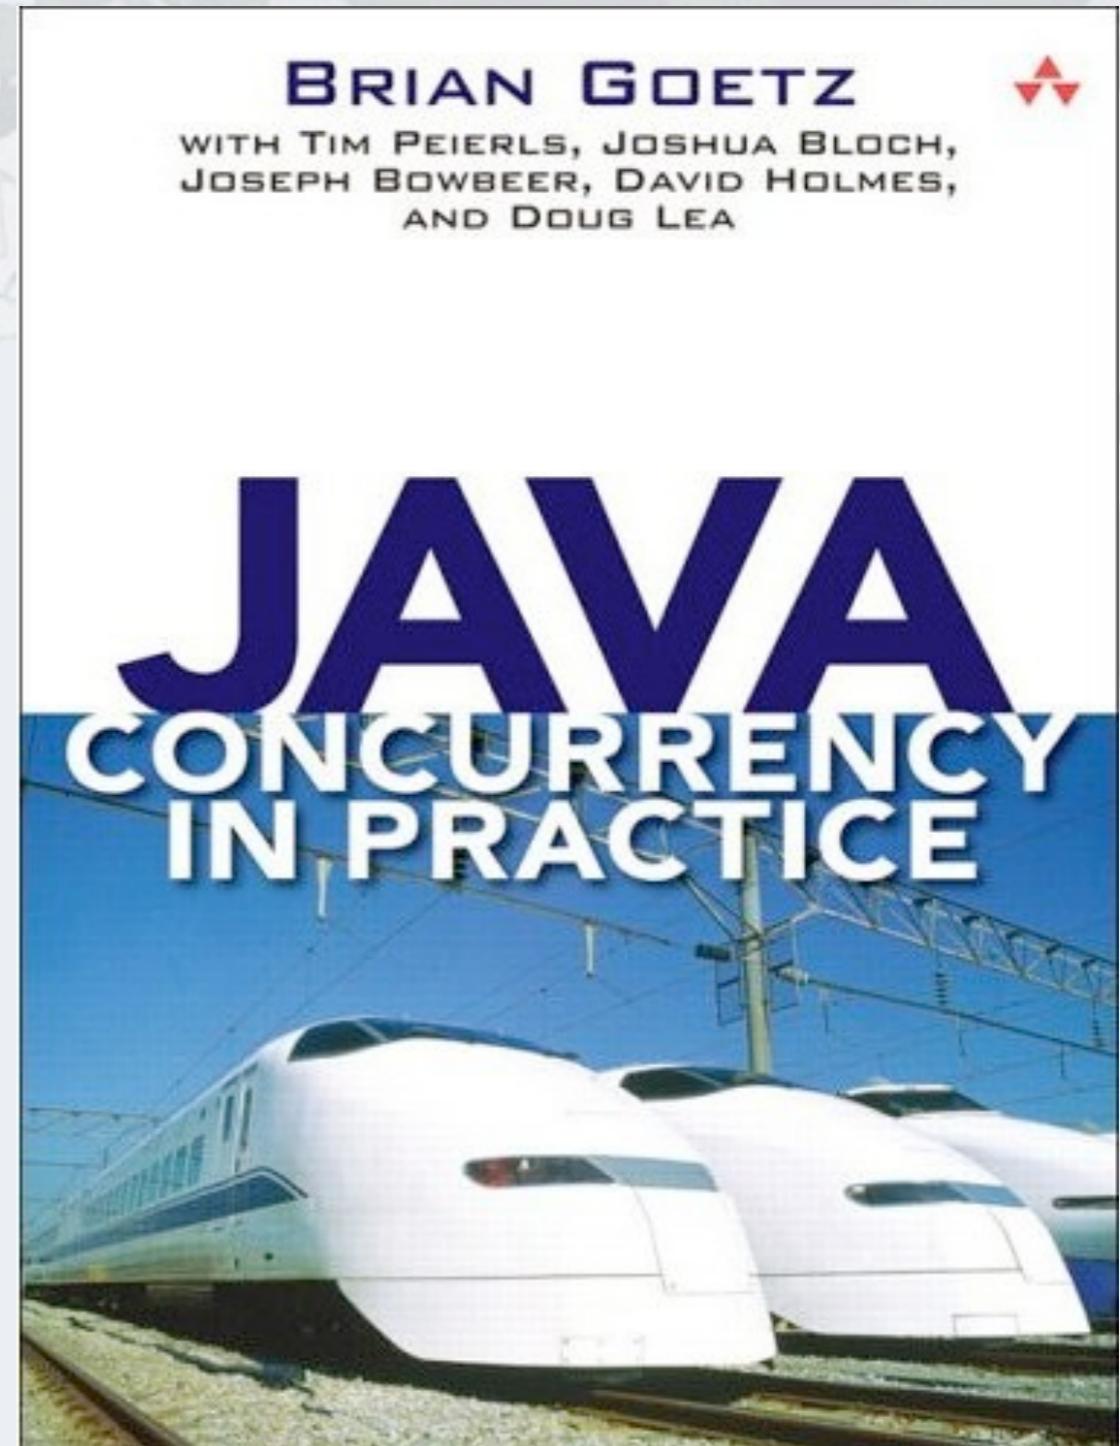

## ● Victor Grazi

- Former salesman from New York
  - Realized early on that programming was more fun than selling!
- Core Java Development at Credit Suisse Client Technology Services
- One of the newest Oracle Java Champions
- Creator of Java Concurrent Animated [www.jconcurrency.com](http://www.jconcurrency.com)

# Short Introduction To Brian Goetz

- Brian Goetz wrote seminal masterpiece "Java Concurrency in Practice"
  - Our recommended book for Java concurrency
  - Course uses this as a basis
- Now is Oracle's "Java Language Architect"
- Most thorough text on how to deal with Java concurrency in everyday work

## Workshop Structure

- **2 x 50 minute lectures, with break in between**
- **1 x 50 minute lab, where you get to solve a liveness issue**
  - Exact time depends on how quick you are
  - Download it from here: <http://tinyurl.com/conc-zip>
- **Your workshop page:**
  - <http://javaspecialists.eu/courses/concurrency/exitcertified.jsp>

## Chat Room

- <http://www.javaspecialists.eu/forum/chat/>
  - We will be in the "Public" channel

Java Specialists Club Chat      AJAX Chat © blueimp.net

Logout Channel: Java\_Design\_Patterns Style: vBulletin Language: English

(18:25:00) kabutz: How can we make a proxy that can run remotely?  
(18:25:07) kabutz: Ummm - dunno!  
(18:25:18) kabutz: At least this chat software works - cool  
(18:27:32) kabutz:  
public class Company {  
 private boolean nonProfit;  
 public void makeMoney() {  
 System.out.println("Make some money");  
 }  
}

**Online users**  
kabutz

# Who Are The Participants

- **Skill level**
  - 31 either complete beginners or no practical experience
  - 124 intermediate
  - 71 advanced programmers
  - 3 super advanced
    - Two of which end their surname in "ev"
  - 38 unspecified
- **Our focus will be mainly on the intermediate and advanced programmers**
  - Will give an introduction to threading, what it is and why we need it

## A Boat Called "Java"

- In Greek, the Latin "J" is translated as "TZ" and "V" as "B"
  - So we get TZABA

# 1: Introduction

## Questions

- Please please please ask questions!
- Interrupt me at any time
  - Type it into chat: <http://www.javaspecialists.eu/forum/chat/>
  - Or put up your hand (little hand icon) and I will unmute you
    - Make sure your microphone volume is turned up
- There are some stupid questions
  - They are the ones you didn't ask
  - Once you've asked them, they are not stupid anymore
- The more you ask, the more we all learn

# The Concurrency Specialist Course

## ● Course Contents

- Introduction
- Thread Safety
- Sharing Objects
- Composing Objects
- Building Blocks
- Task Execution
- Cancellation and Shutdown
- Applying Thread Pools
- SwingWorker and Fork/Join
- **Avoiding Liveness Hazards**
- Performance and Scalability
- Testing Concurrent Programs
- Building Custom Synchronizers

- <http://www.javaspecialists.eu/courses/concurrency.jsp>

## Multiple Processes

- **Time slicing allows us to run many programs at once**
  - Illusion; our O/S swaps between different processes very quickly
- **Each process typically runs in its own memory space**
  - Inter-process communication is expensive

# Why Use Threads?

- Threads are software abstractions to help us utilize the available hardware
- Threads are like lightweight processes, sharing the same memory space
- Quick for scheduler to swap between threads
- Performance can improve if we utilize all the cores
- Threading can also simplify coding
  - Our systems can be written with better OO principles
  - Independent workflows do not have to know about each other

## Let's Go Fast Fast Fast

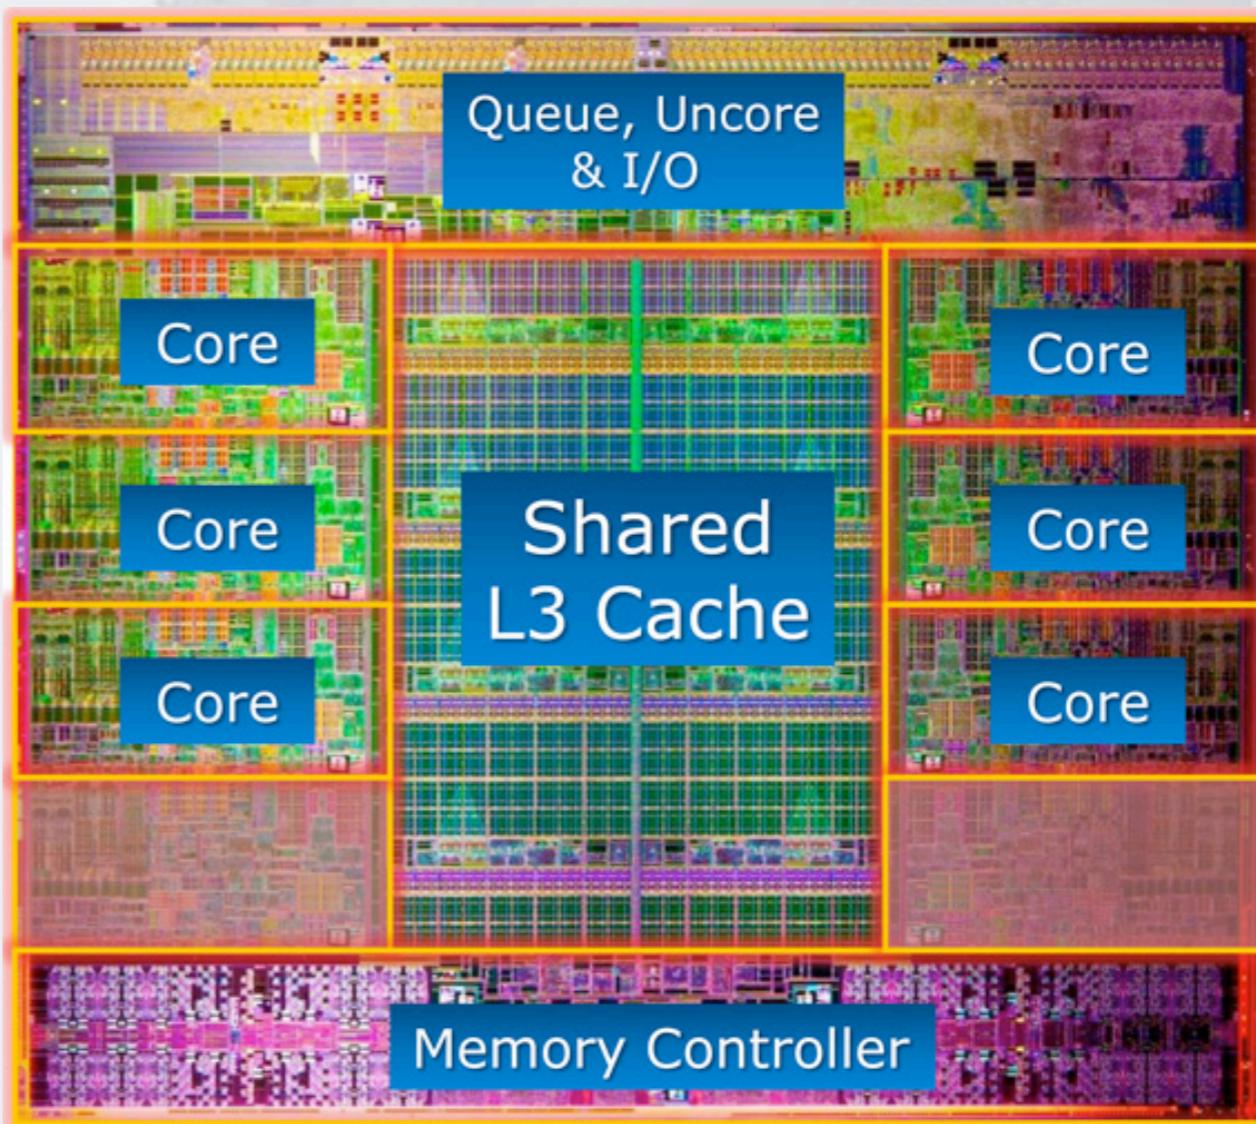

- In 2000, Intel predicted 10GHz chips on desktop by 2011
  - <http://www.zdnet.com/news/taking-chips-to-10ghz-and-beyond/96055>
- Core i7 990x hit the market early 2011
  - 3.46GHz clock stretching up to 3.73 GHz in turbo mode
  - 6 processing cores
  - Running in parallel, we get 22GHz of processing power!

## Moore's Law

- Stated in 1965 that for the next 10 years, the *number or transistors would double every two years*
  - The prediction was only made for 10 years, but it is still true today
- Clock speed has leveled off
  - Heat buildup means we struggle to go beyond 4GHz
  - Moore's Law has often been misunderstood as *clock speed doubling every 2 years*
- The way to scale is to have lots of cores working together

# CPU / Core / Hardware Thread

- The Intel i7-3960X
- One CPU socket
- Six activated cores
- Each core supports two hyperthreads
  - Each core can only execute a single instruction at a time, but the data is fetched in parallel
- Total of 12 threads
- `Runtime.getRuntime().availableProcessors() = 12`

## Japanese 'K' Computer

- In June 2011, could calculate 8.2 petaFLOPS
  - 8 200 000 000 000 floating point operations per second
  - Intel 8087 was 30 000 FLOPS, 273 billion times slower
  - 548,352 cores from 68,544 2GHz 8-Core SPARC64 VIIIfx processors
- By November 2011, it had surpassed 10 petaFLOPS

## "Sequoia" At Lawrence Livermore National Lab

- Used by USA's National Nuclear Security Administration to simulate nuclear bombs
- June 2012: Delivers 16 petaflops
  - 1.6 million cores
  - 1.6 petabytes of memory

## Utilization Of Hardware

- Threading is software abstraction to keep hardware busy
  - Otherwise, why put up with safety and liveness issues?
- We want to utilize all our CPUs with application code
  - Having too many serial sections means that not all CPUs are working

- Too much locking means we are busy with system code

# Threading Models

- **Preemptive multithreading (Native Threads)**
  - Operating system is responsible for forcing a context switch
  - Threads can be swapped in the middle of an operation
    - For example half-way through  $\text{balance} = \text{balance} + 100$
- **Cooperative multithreading (Green Threads)**
  - Threads give up control at a stopping point
    - Yield, sleep, wait
  - Infinite loops could never give up control
- **Which One?**
  - Preemptive (native) is safer, but we get race conditions
  - In modern JDKs, preemptive is used

# 10: Avoiding Liveness Hazards

Safety first!

JavaSpecialists.eu  
java training

# 10: Avoiding Liveness Hazards

- Fixing safety problems can cause liveness problems
  - Don't indiscriminately sprinkle "synchronized" into your code
- Liveness hazards can happen through
  - Lock-ordering deadlocks
    - Typically when you lock two locks in different orders
    - Requires global analysis to make sure your order is consistent
      - Lesson: only ever hold a single lock per thread!
  - Resource deadlocks
    - This can happen with bounded queues or similar mechanisms meant to bound resource consumption

# 10.1 Deadlock

Avoiding Liveness Hazards

Javaspecialists.eu  
java training

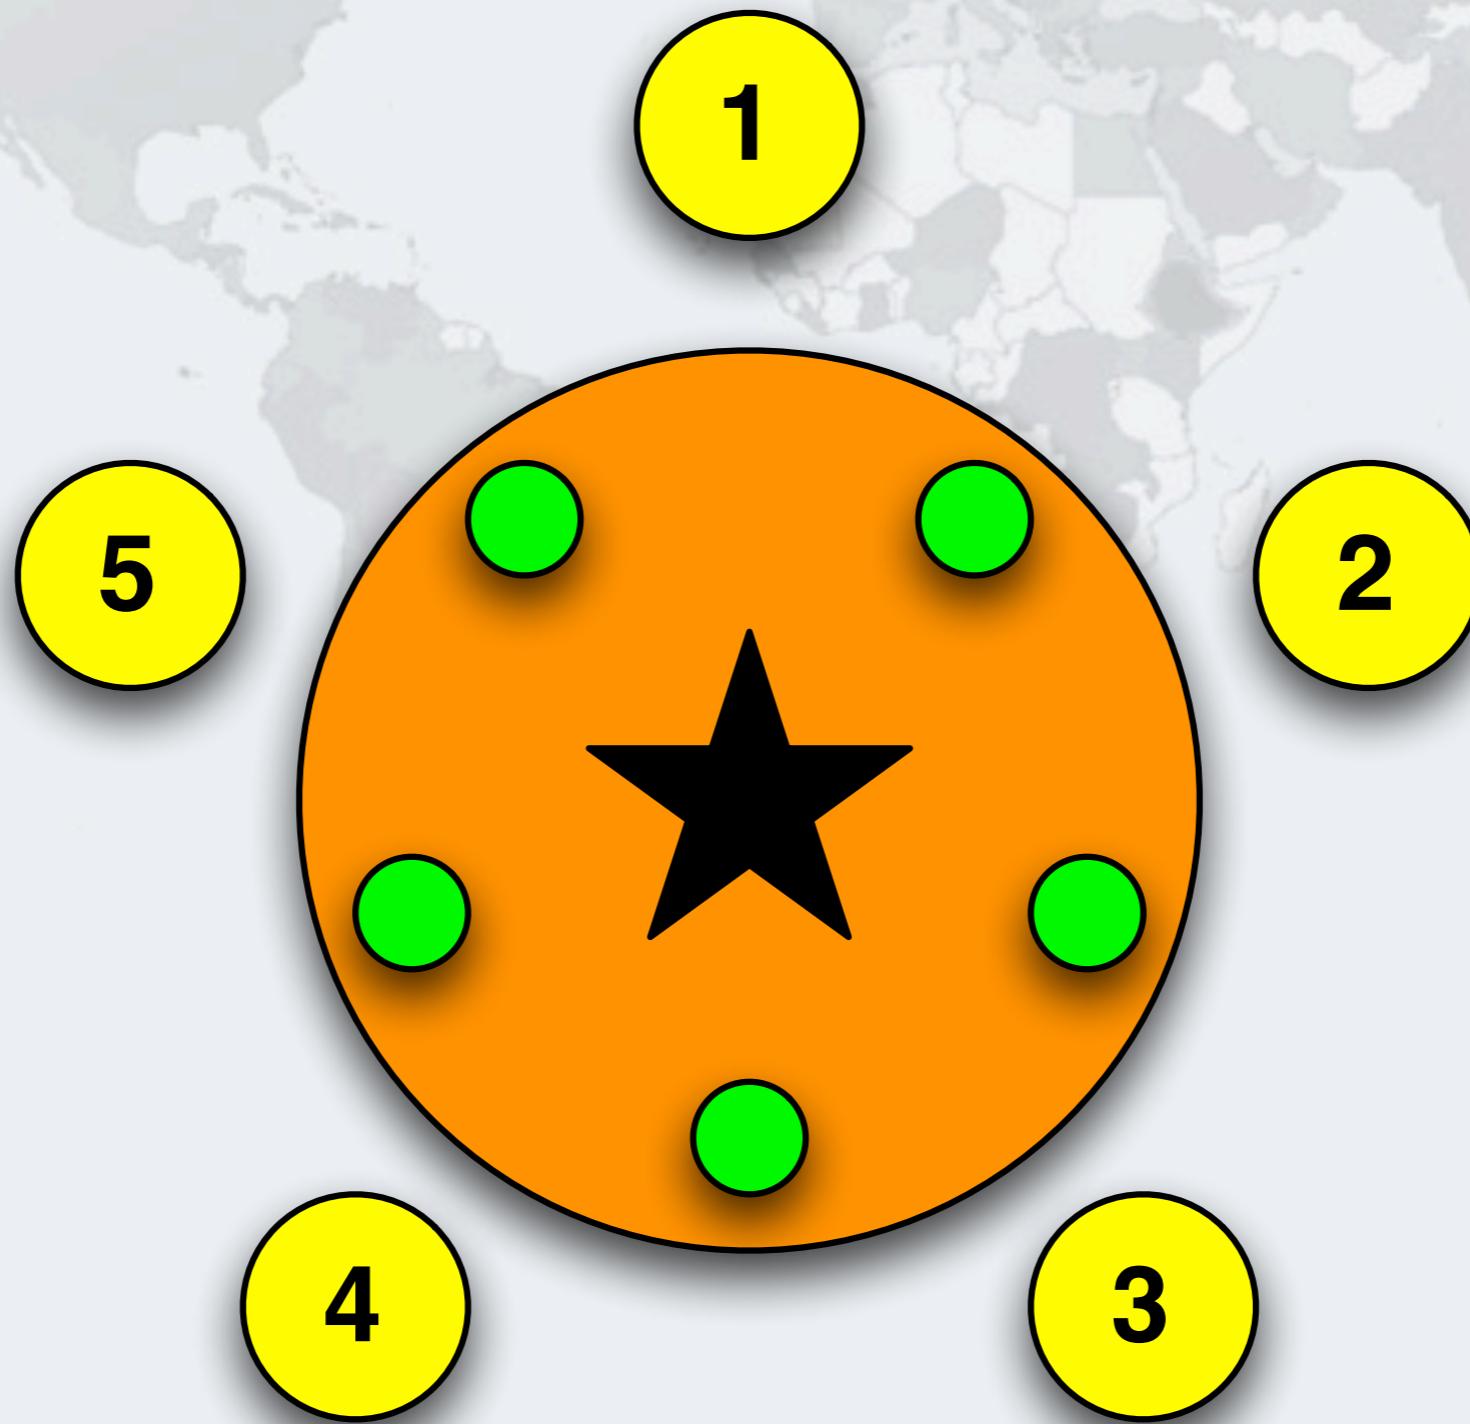

## 10.1 Deadlock

- **Classic problem is that of the "dining philosophers"**
  - We changed that to the "drinking philosophers"
    - That is where the word "symposium" comes from
      - sym - together, such as "symphony"
      - poto - drink
    - Ancient Greek philosophers used to get together to drink & think
- **In our example, a philosopher needs two glasses to drink**
  - First he takes the right one, then the left one
  - When he finishes drinking, he returns them and carries on thinking

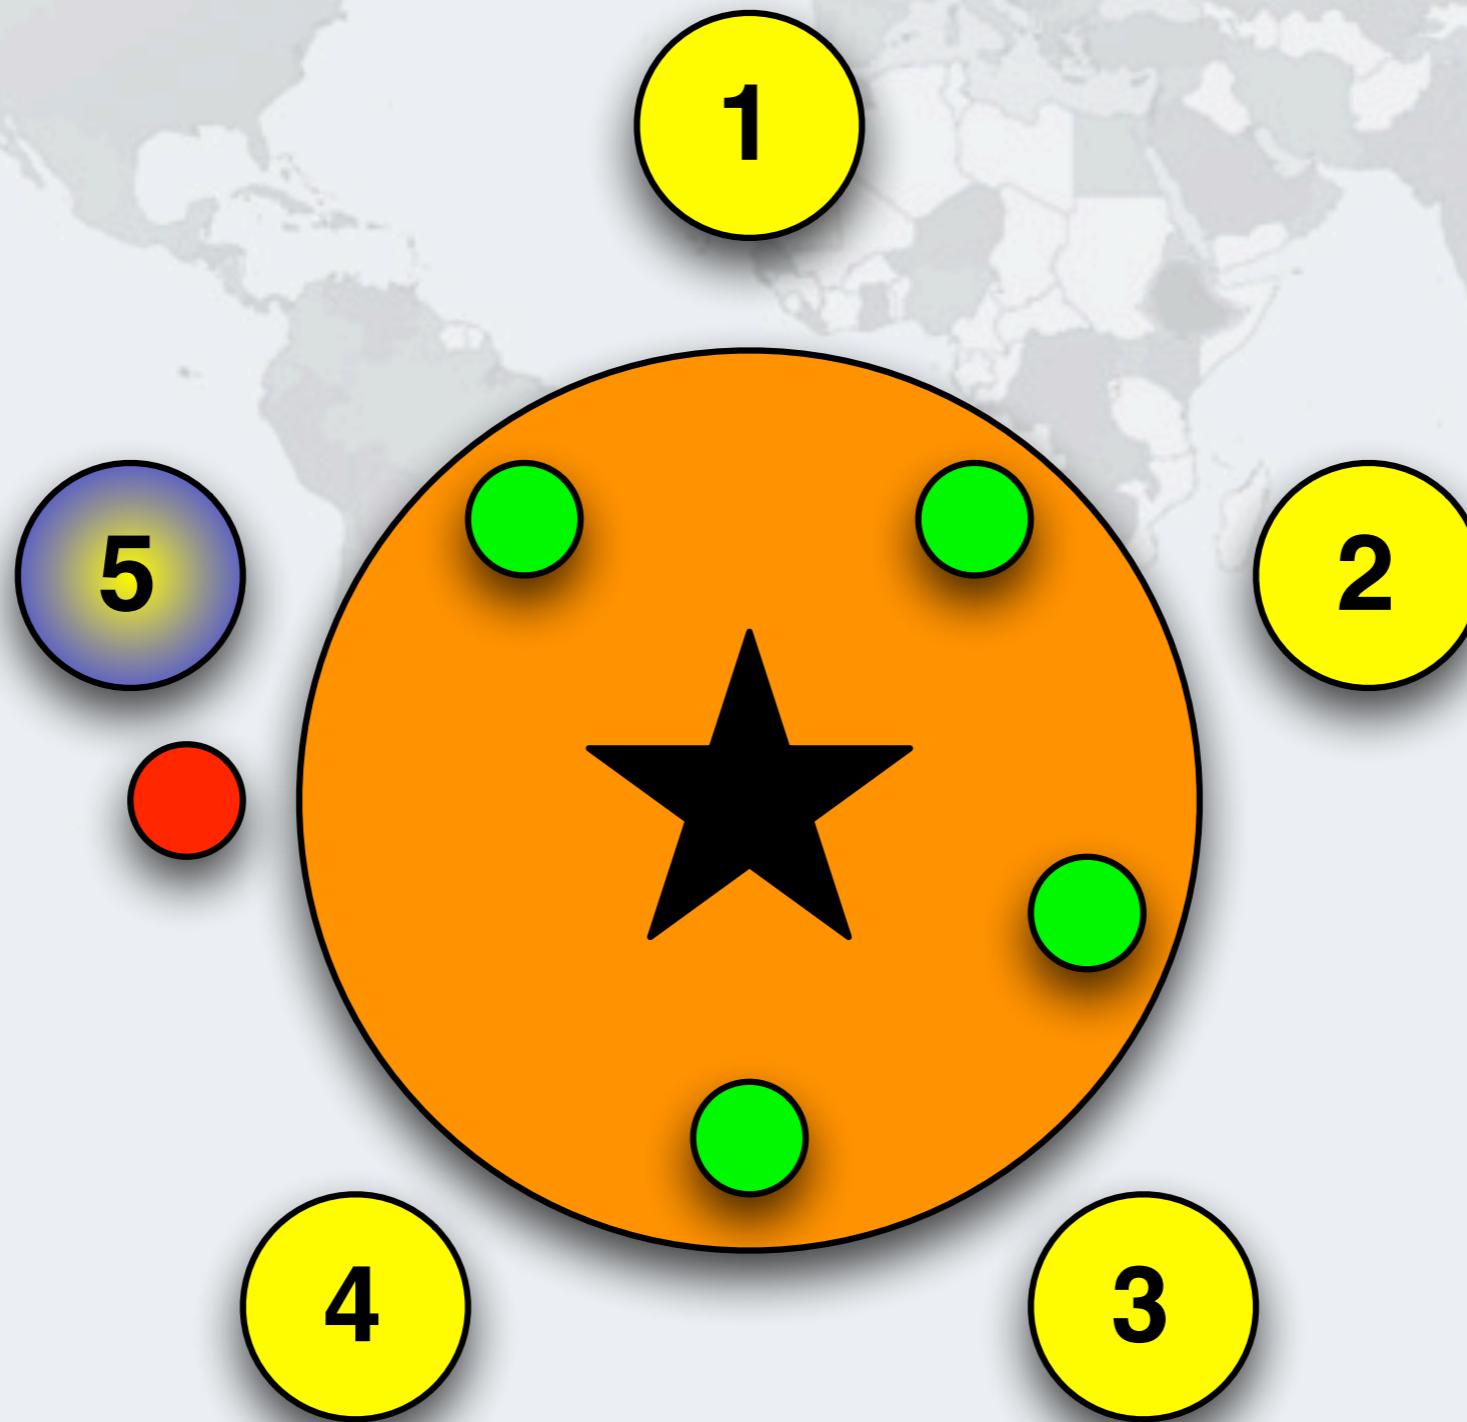

## Legends For Example

- Thinking philosopher 
- Drinking philosopher 
- Changing state philosopher 
- Available cup 
- Taken cup 

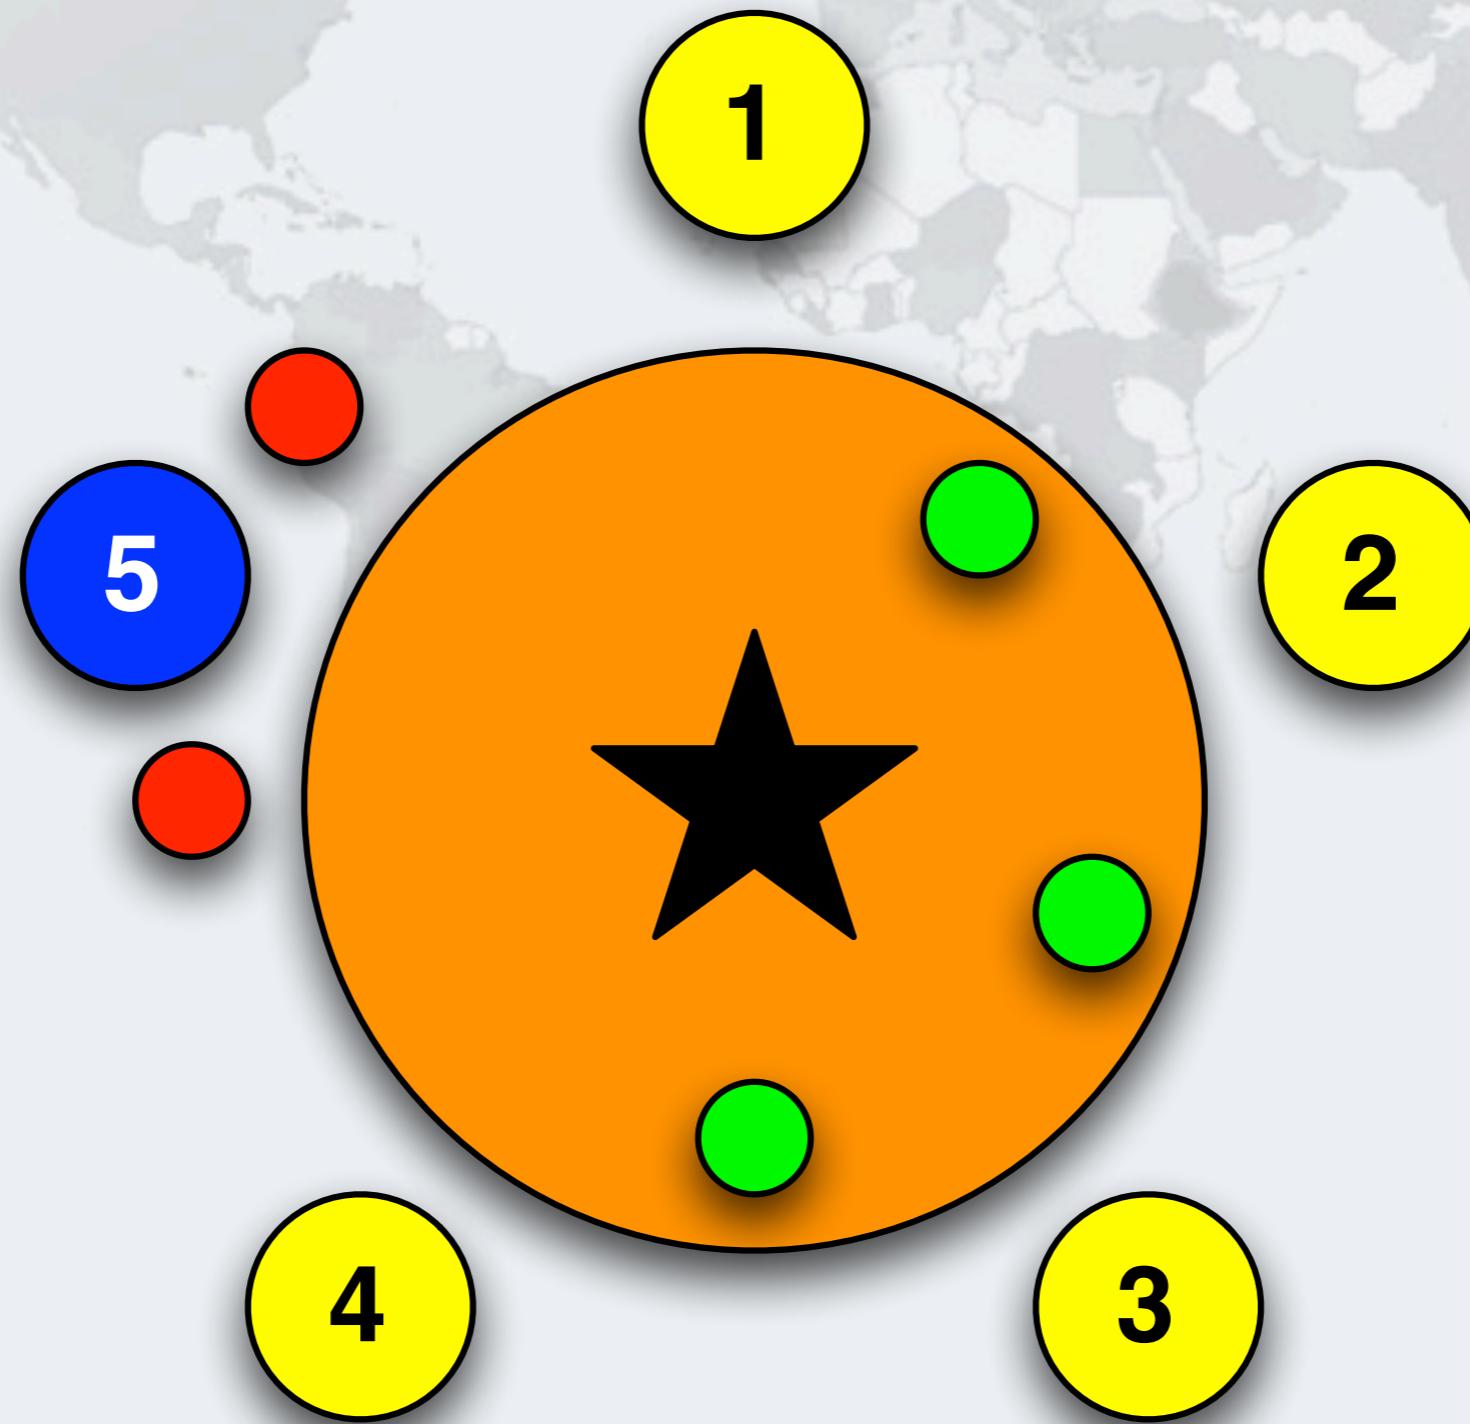

# Table Is Ready, All Philosophers Are Thinking

# Philosophers 5 Wants To Drink, Takes Right Cup

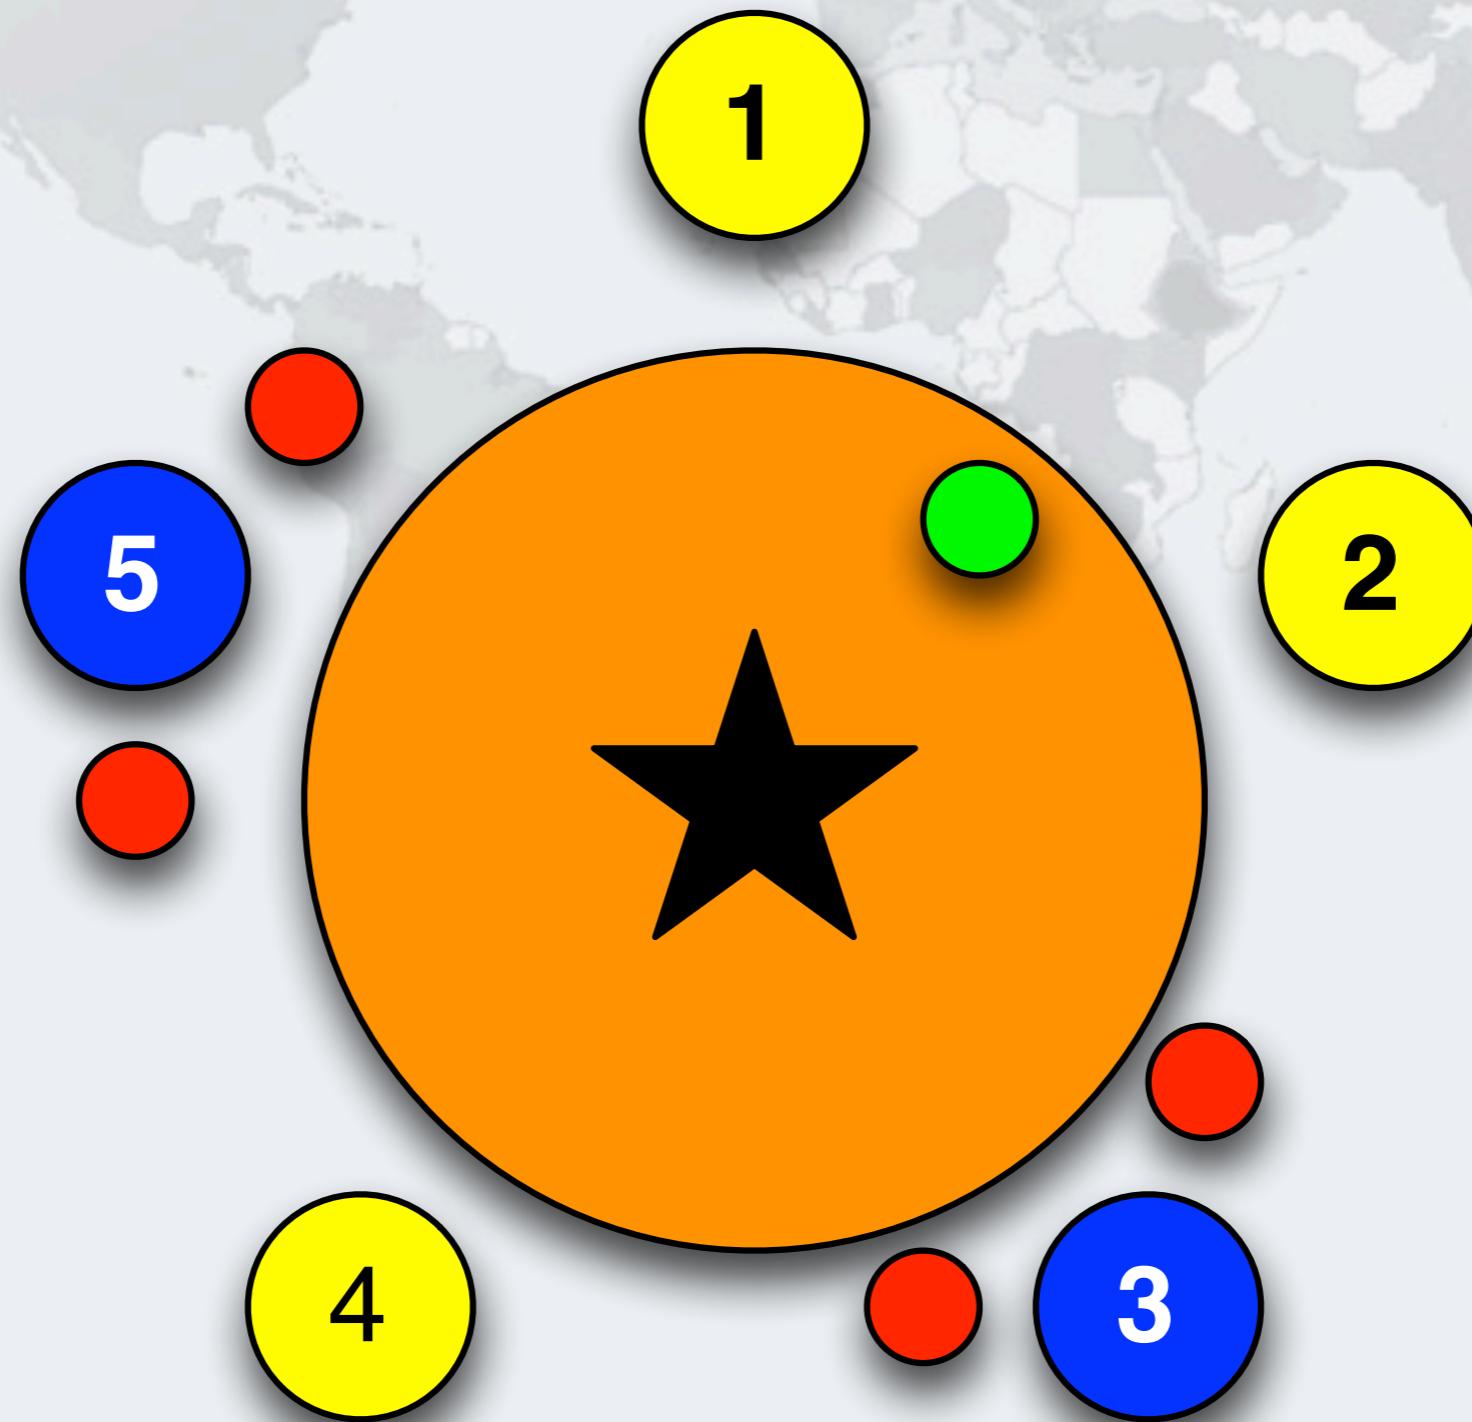

# Philosopher 5 Is Now Drinking With Both Cups

# Philosophers 3 Wants To Drink, Takes Right Cup

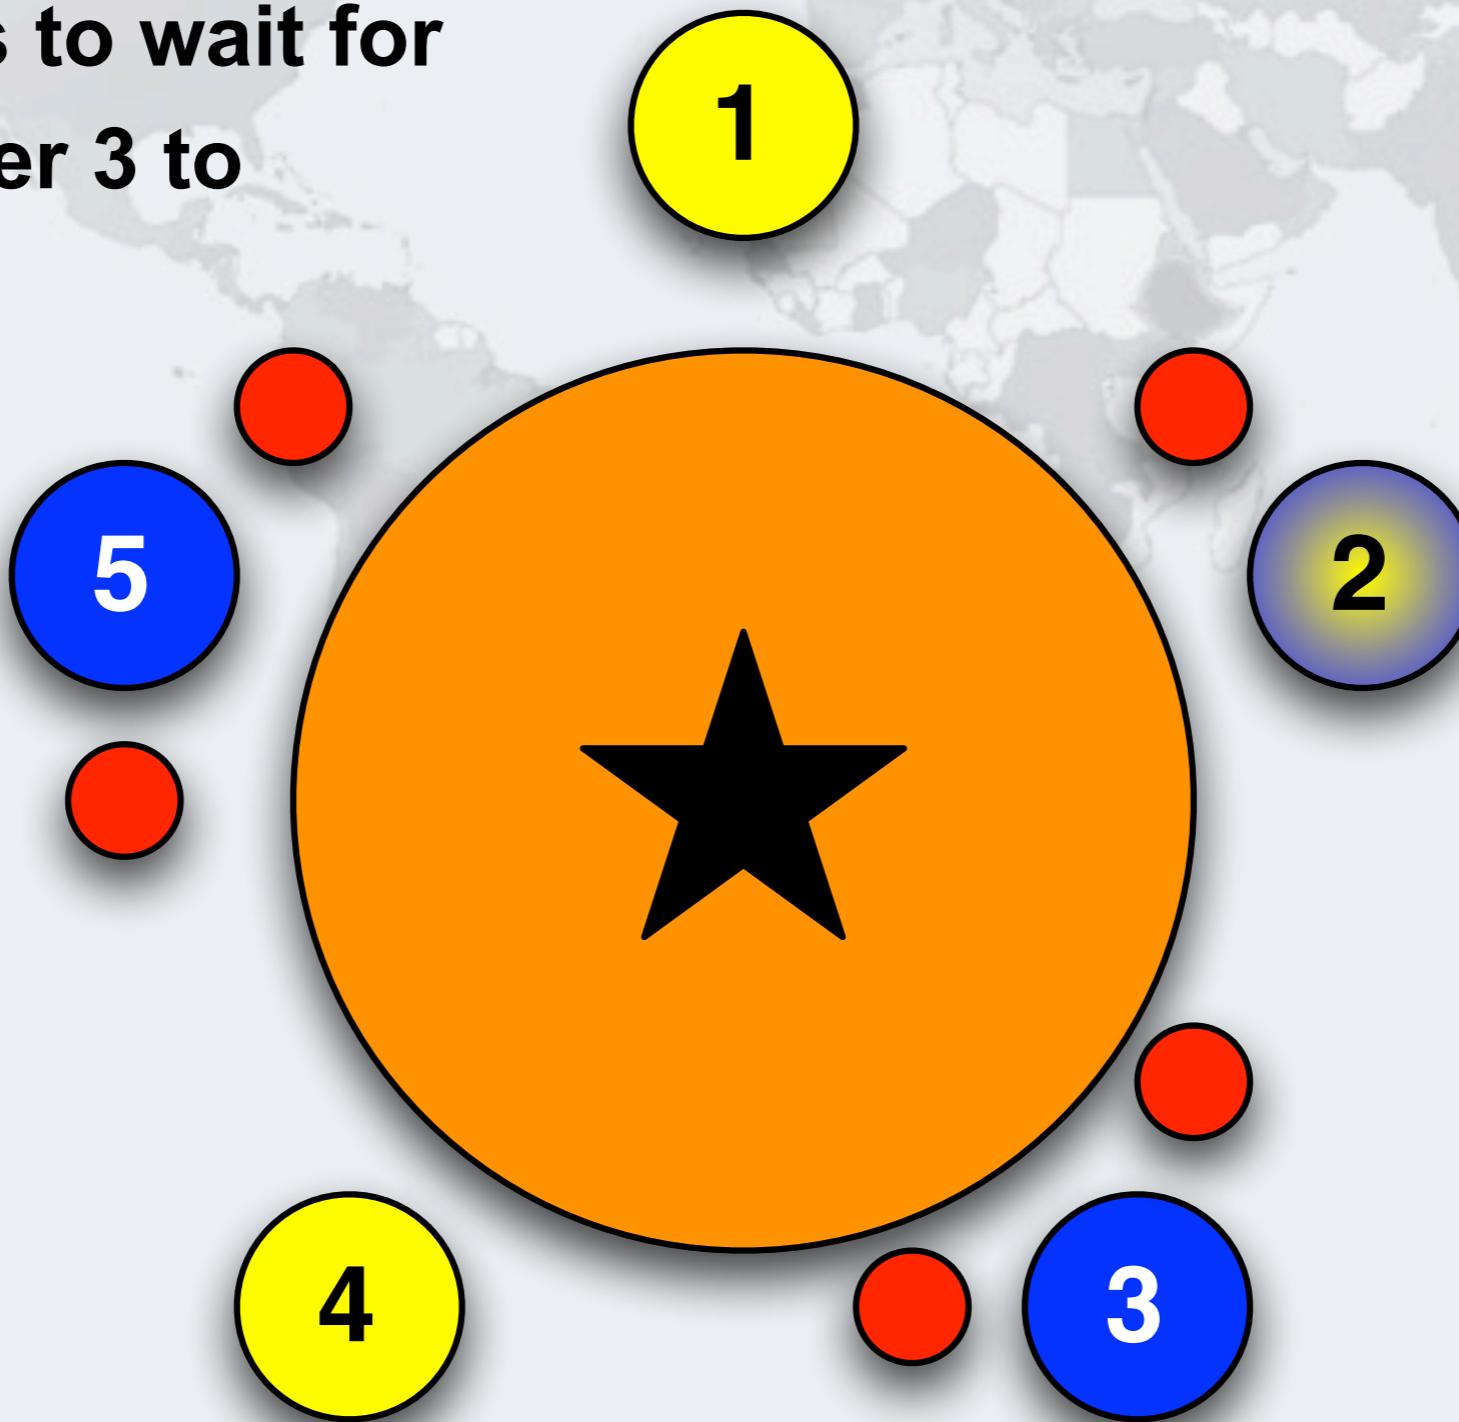

# Philosopher 3 Is Now Drinking With Both Cups

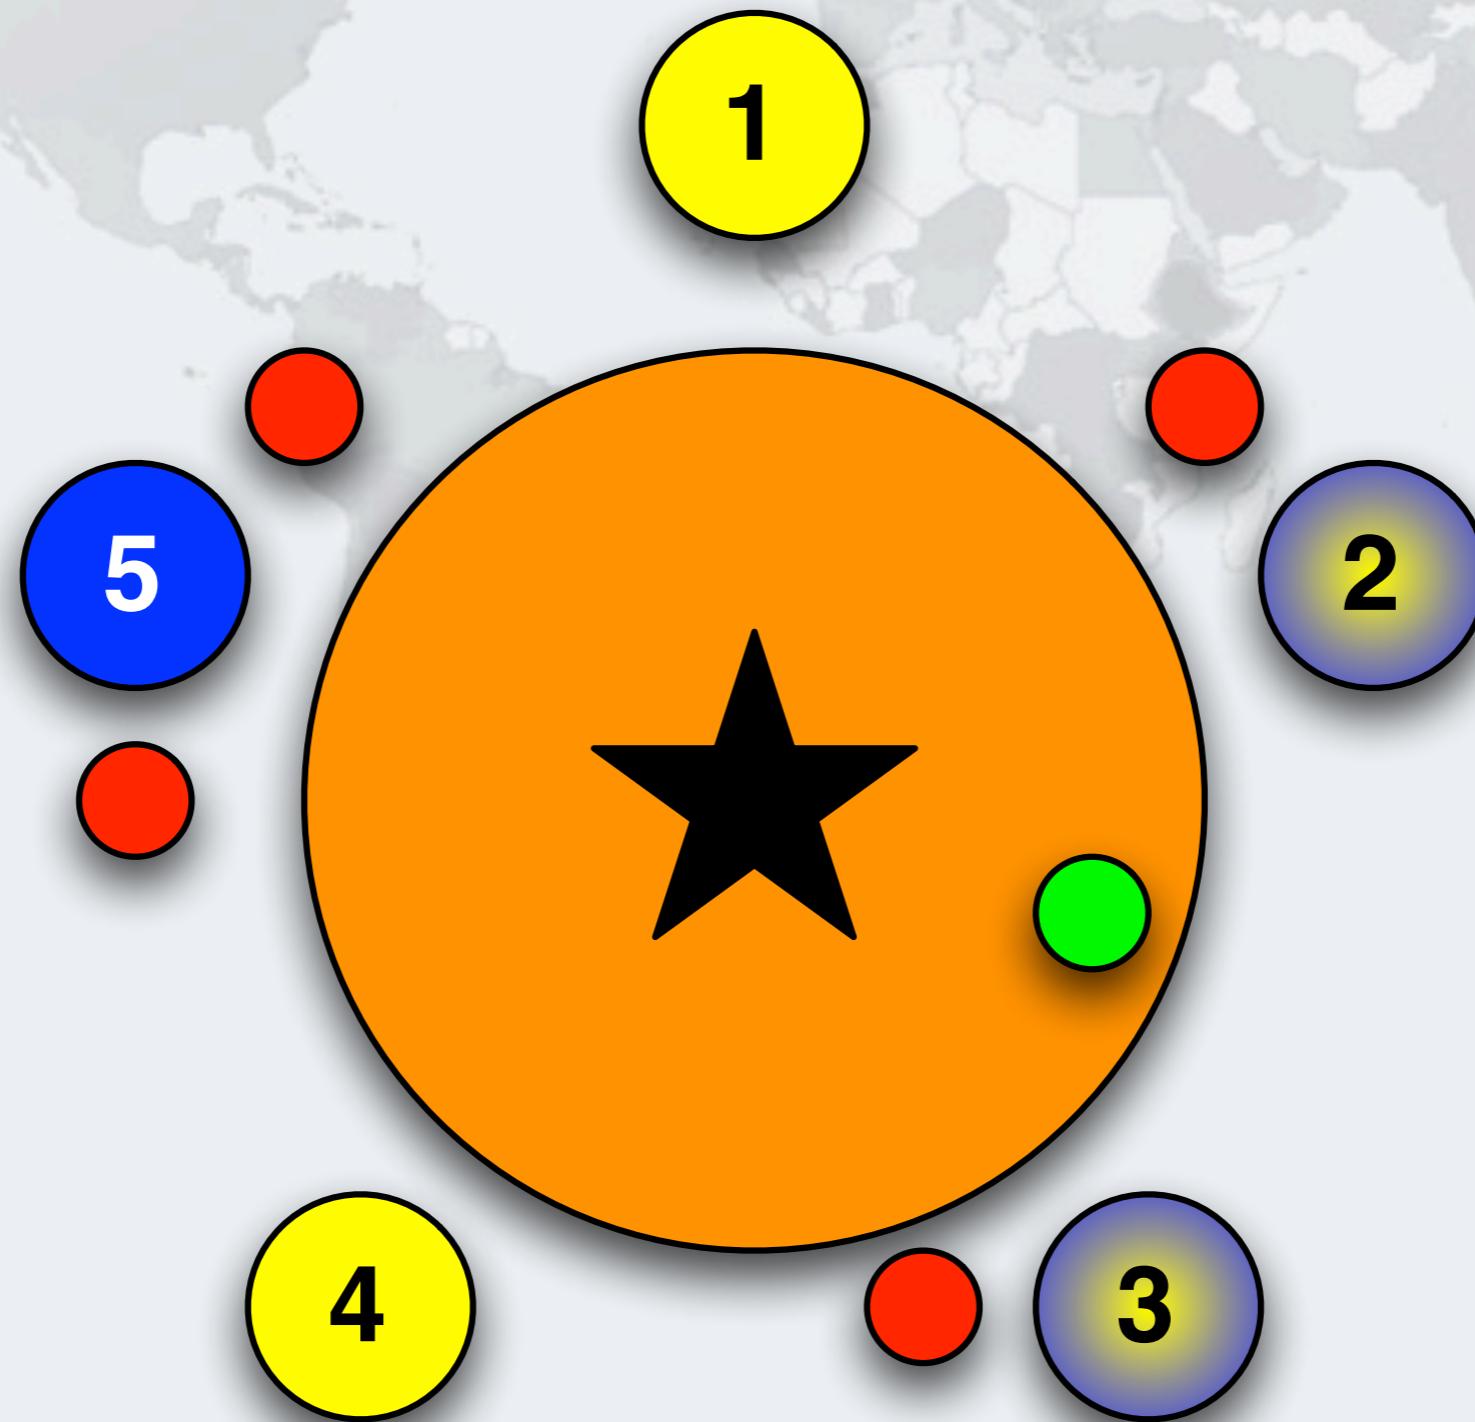

## Philosophers 2 Wants To Drink, Takes Right Cup

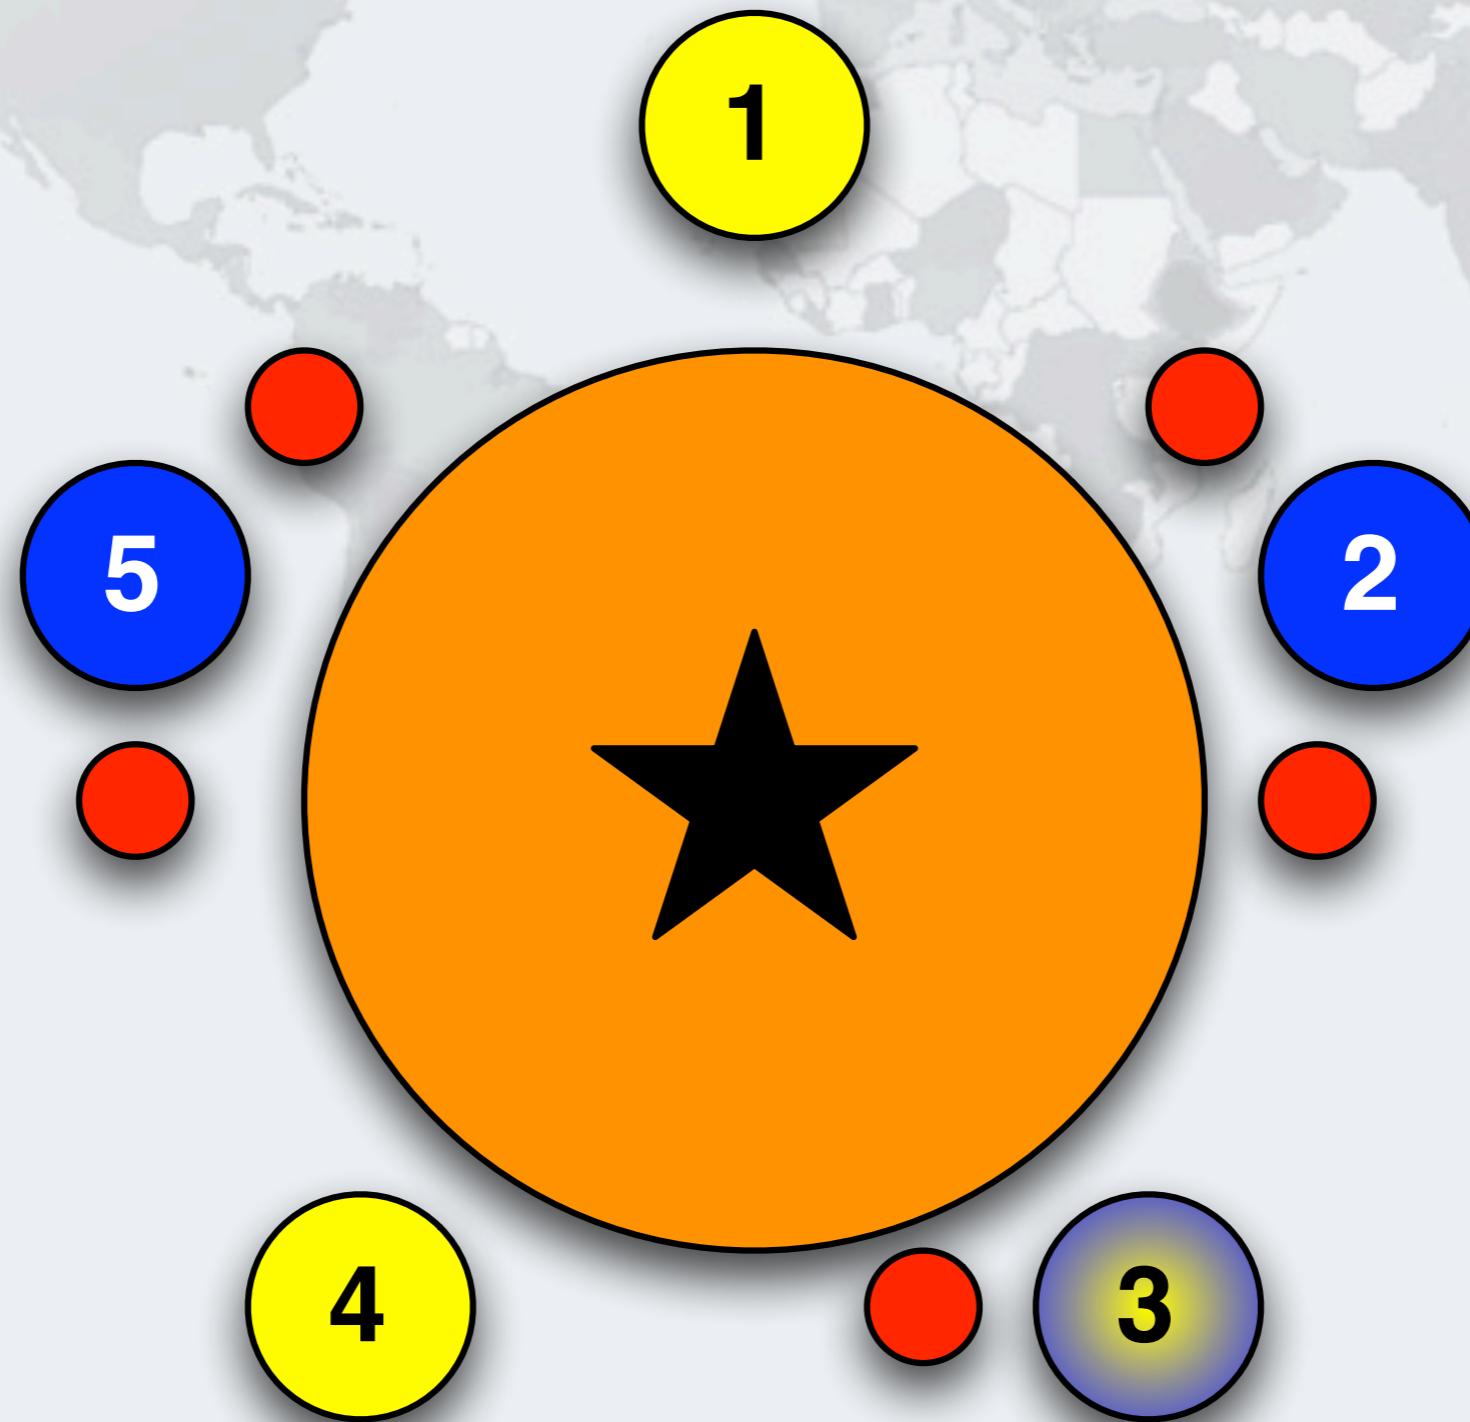

- But he has to wait for Philosopher 3 to finish his drinking session

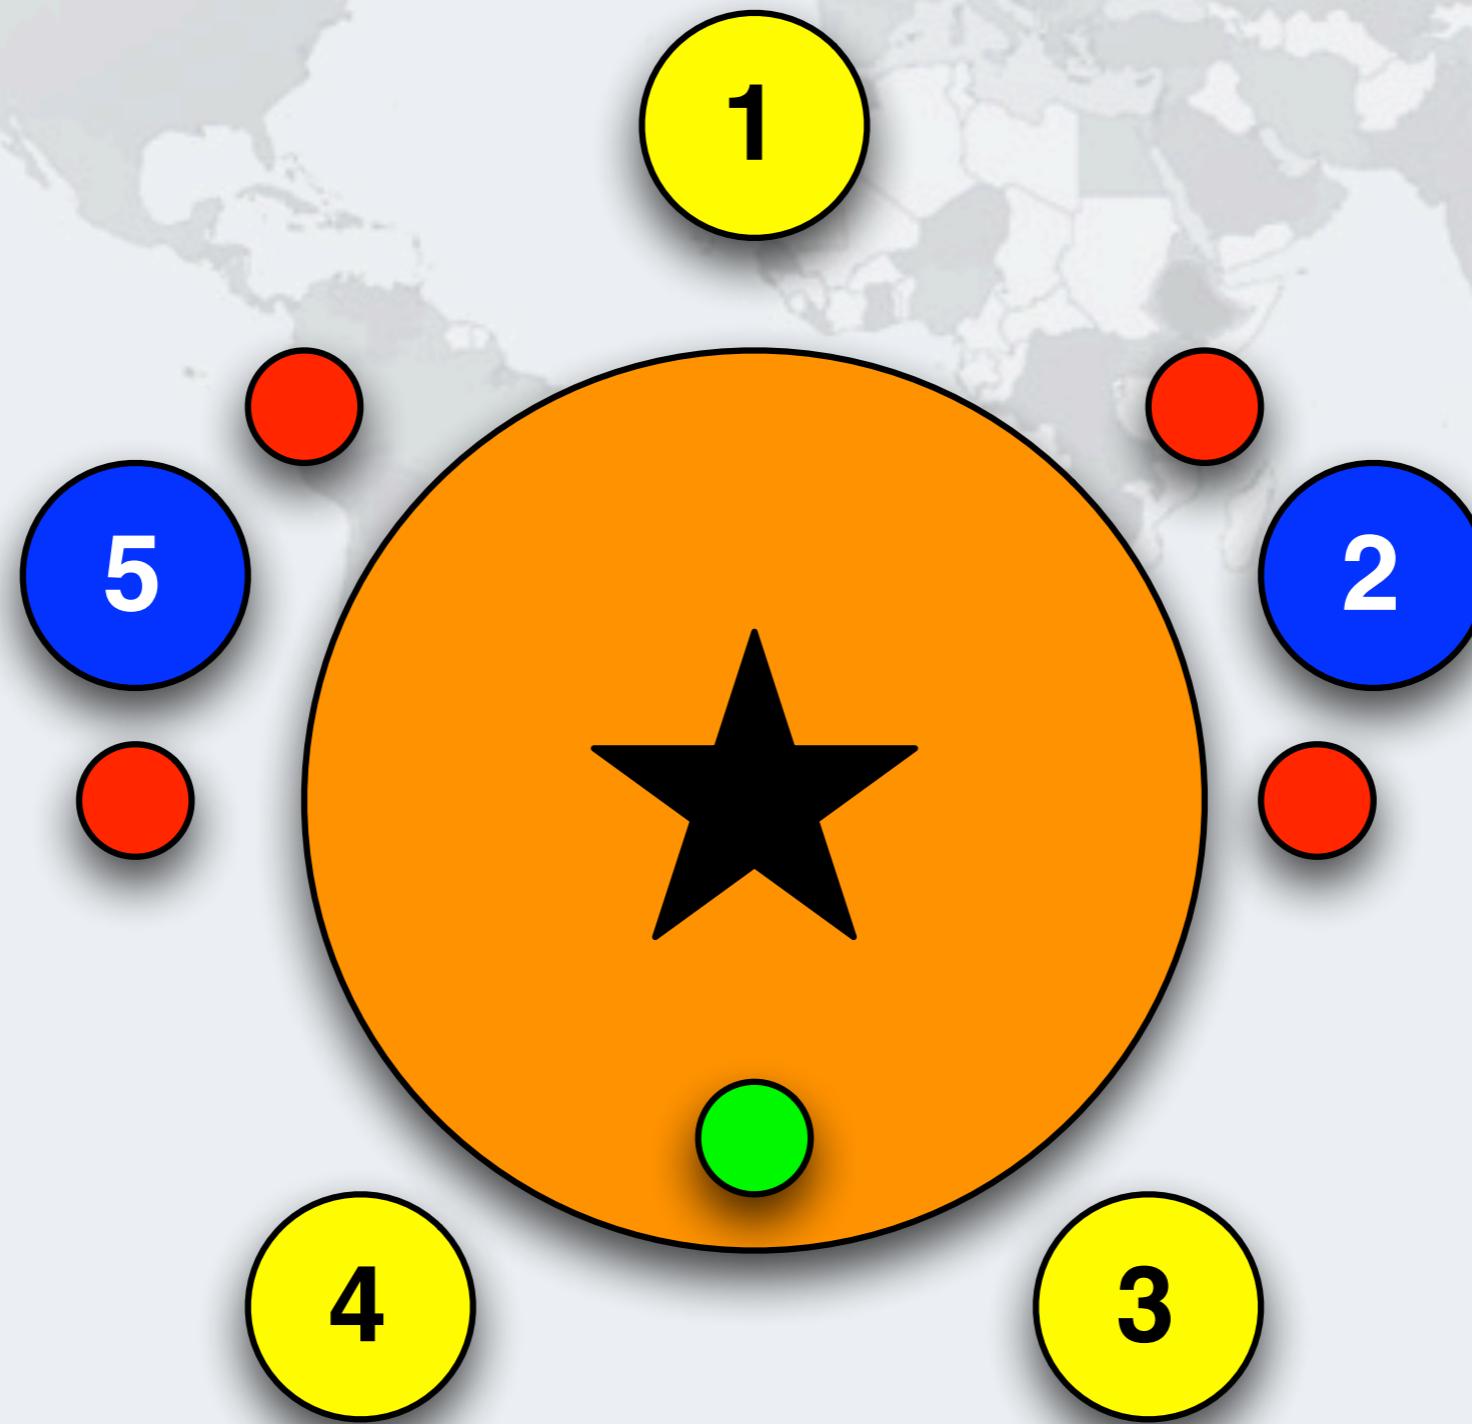

# Philosopher 3 Finished Drinking, Returns Right Cup

# Philosopher 2 Is Now Drinking With Both Cups

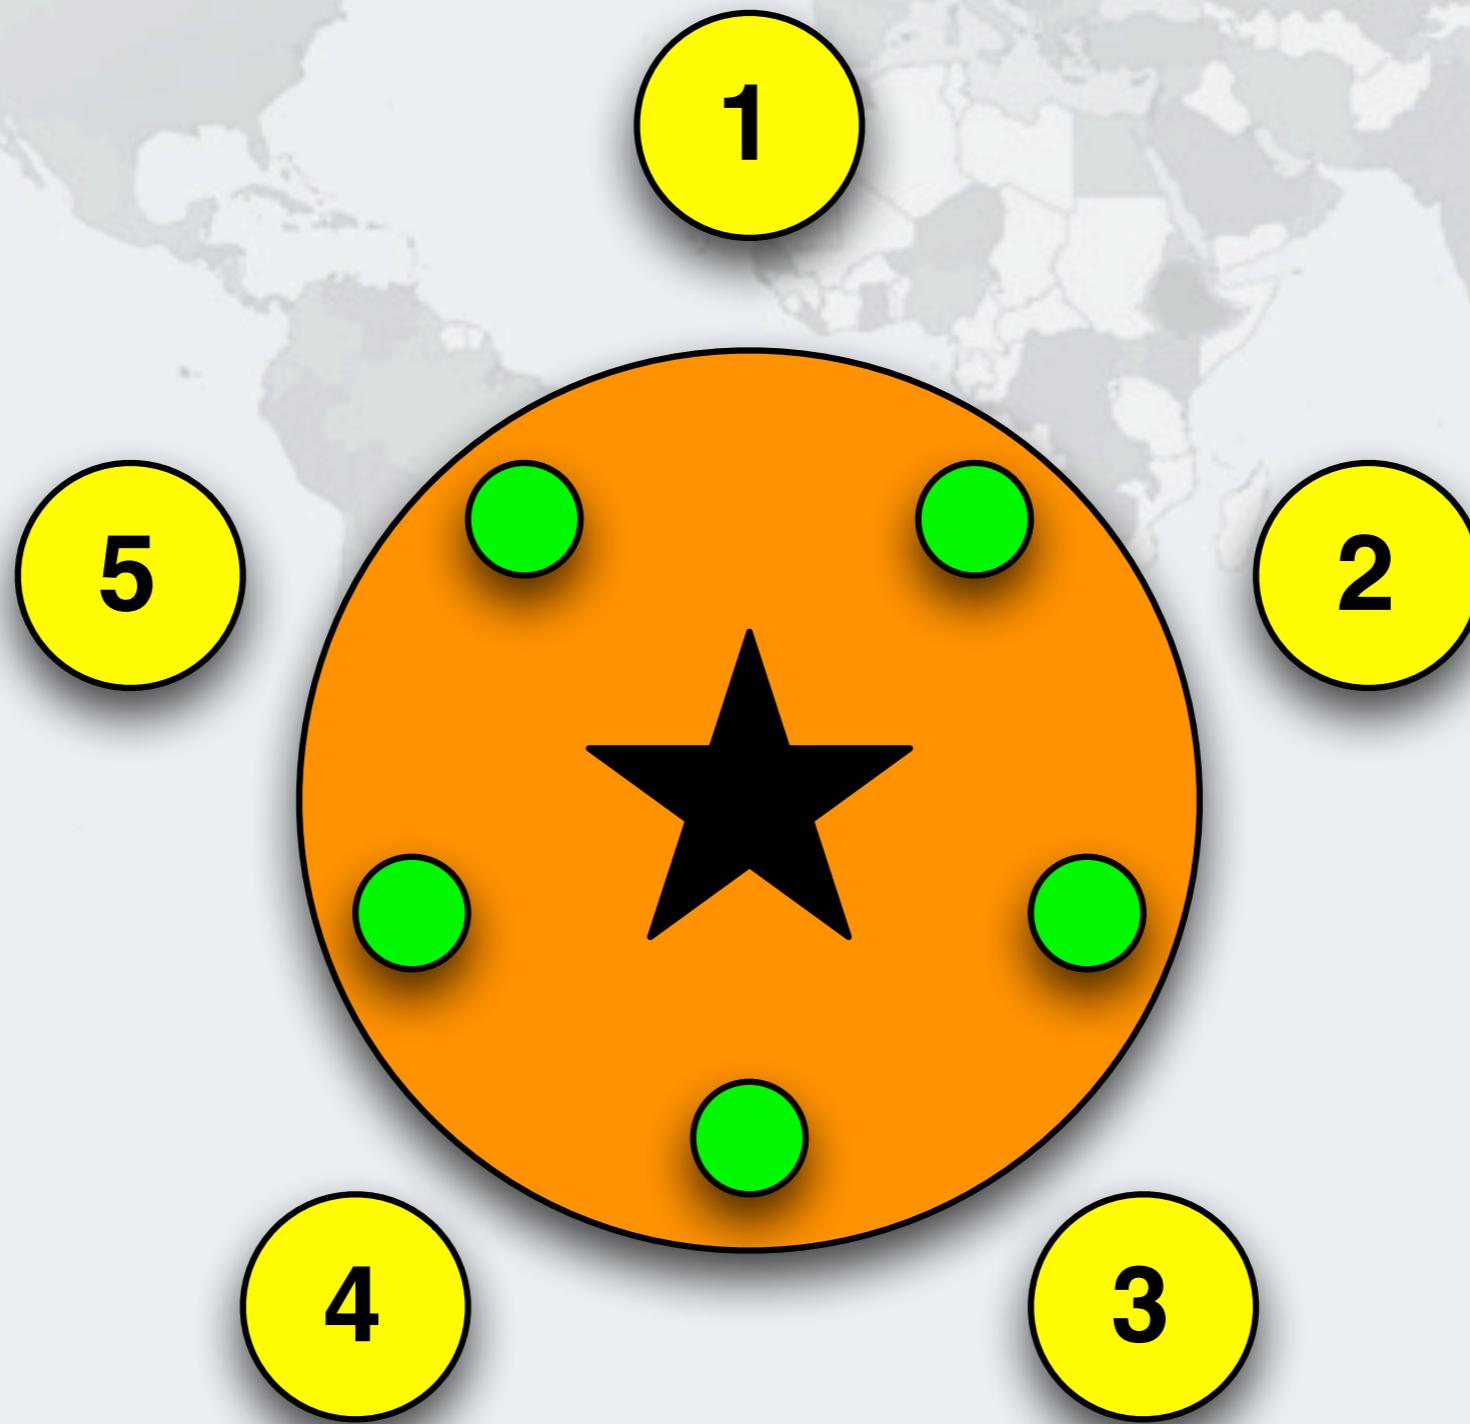

# Philosopher 3 Returns Left Cup

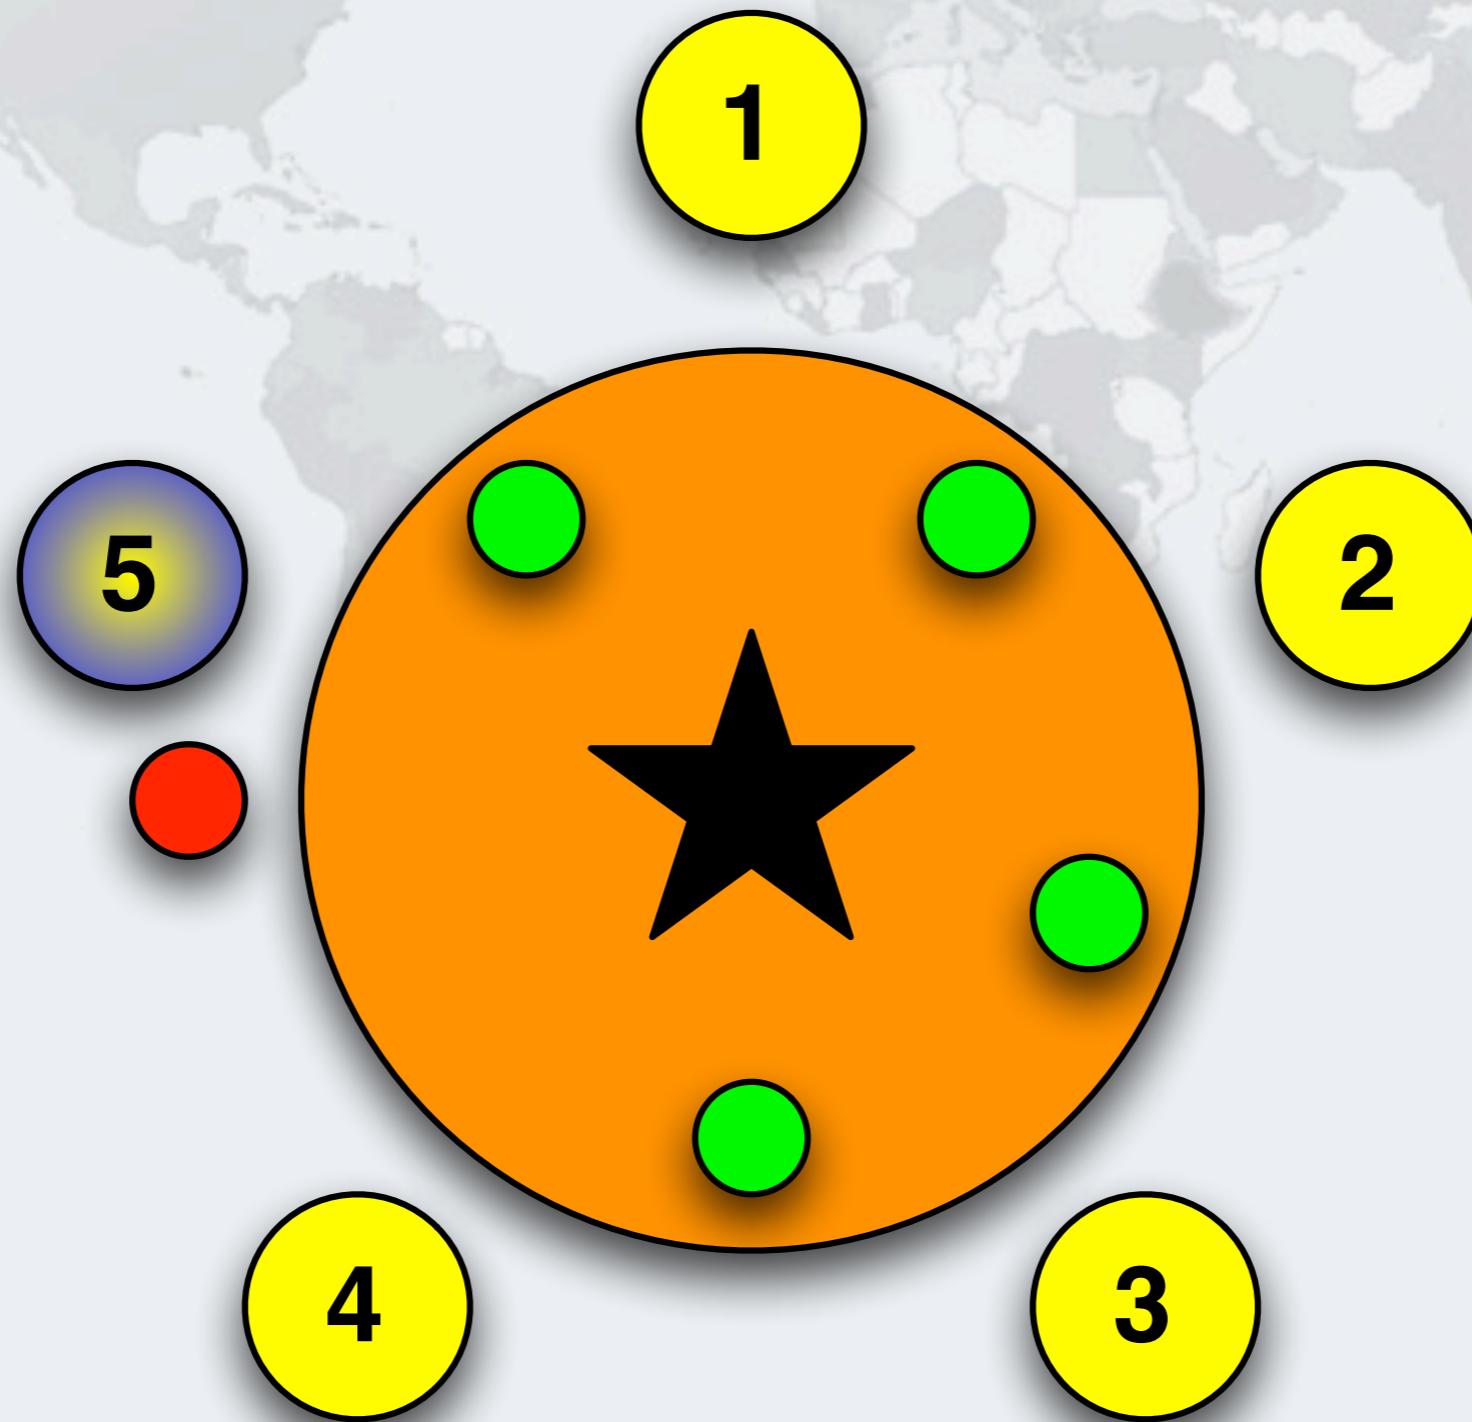

## Drinking Philosophers In Limbo

- The standard rule is that every philosopher first picks up the right cup, then the left
  - If all of the philosophers want to drink and they all pick up the right cup, then they all are holding one cup but cannot get the left cup

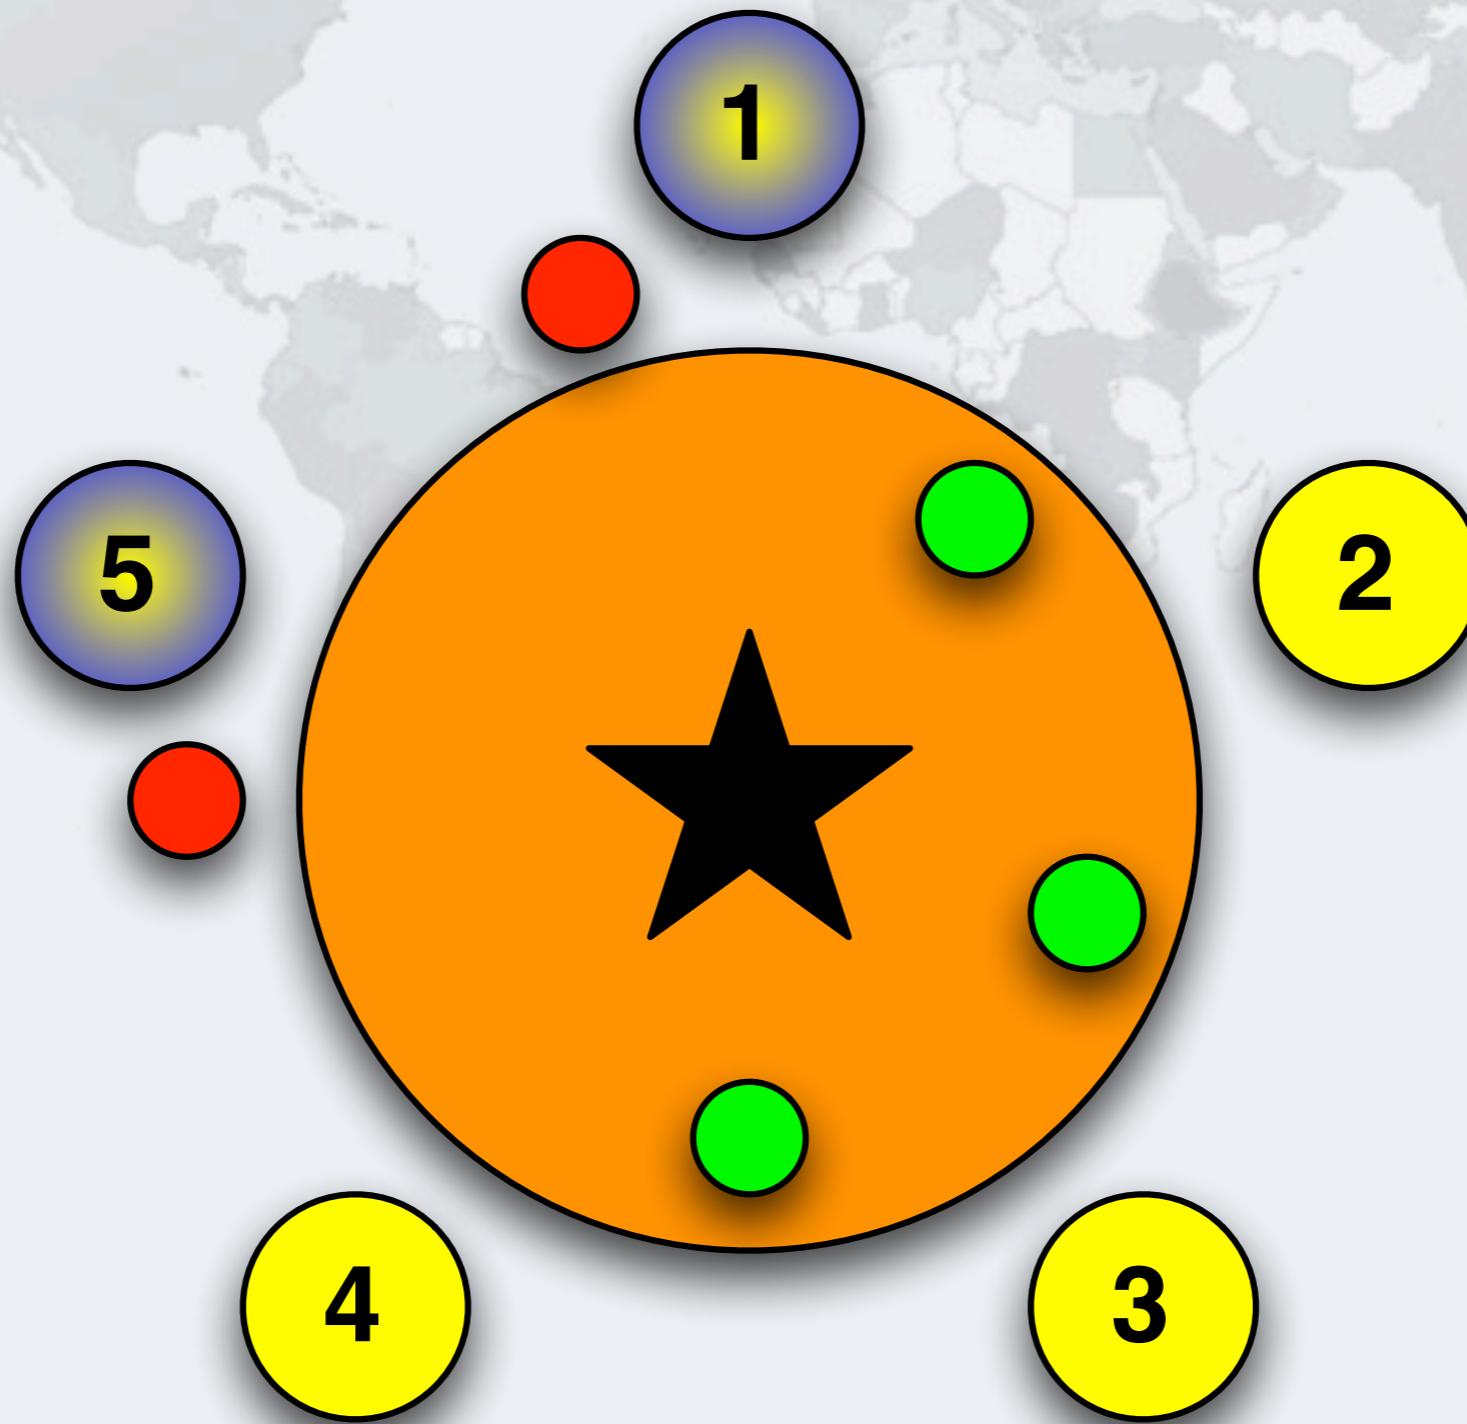

# A Deadlock Can Easily Happen With This Design

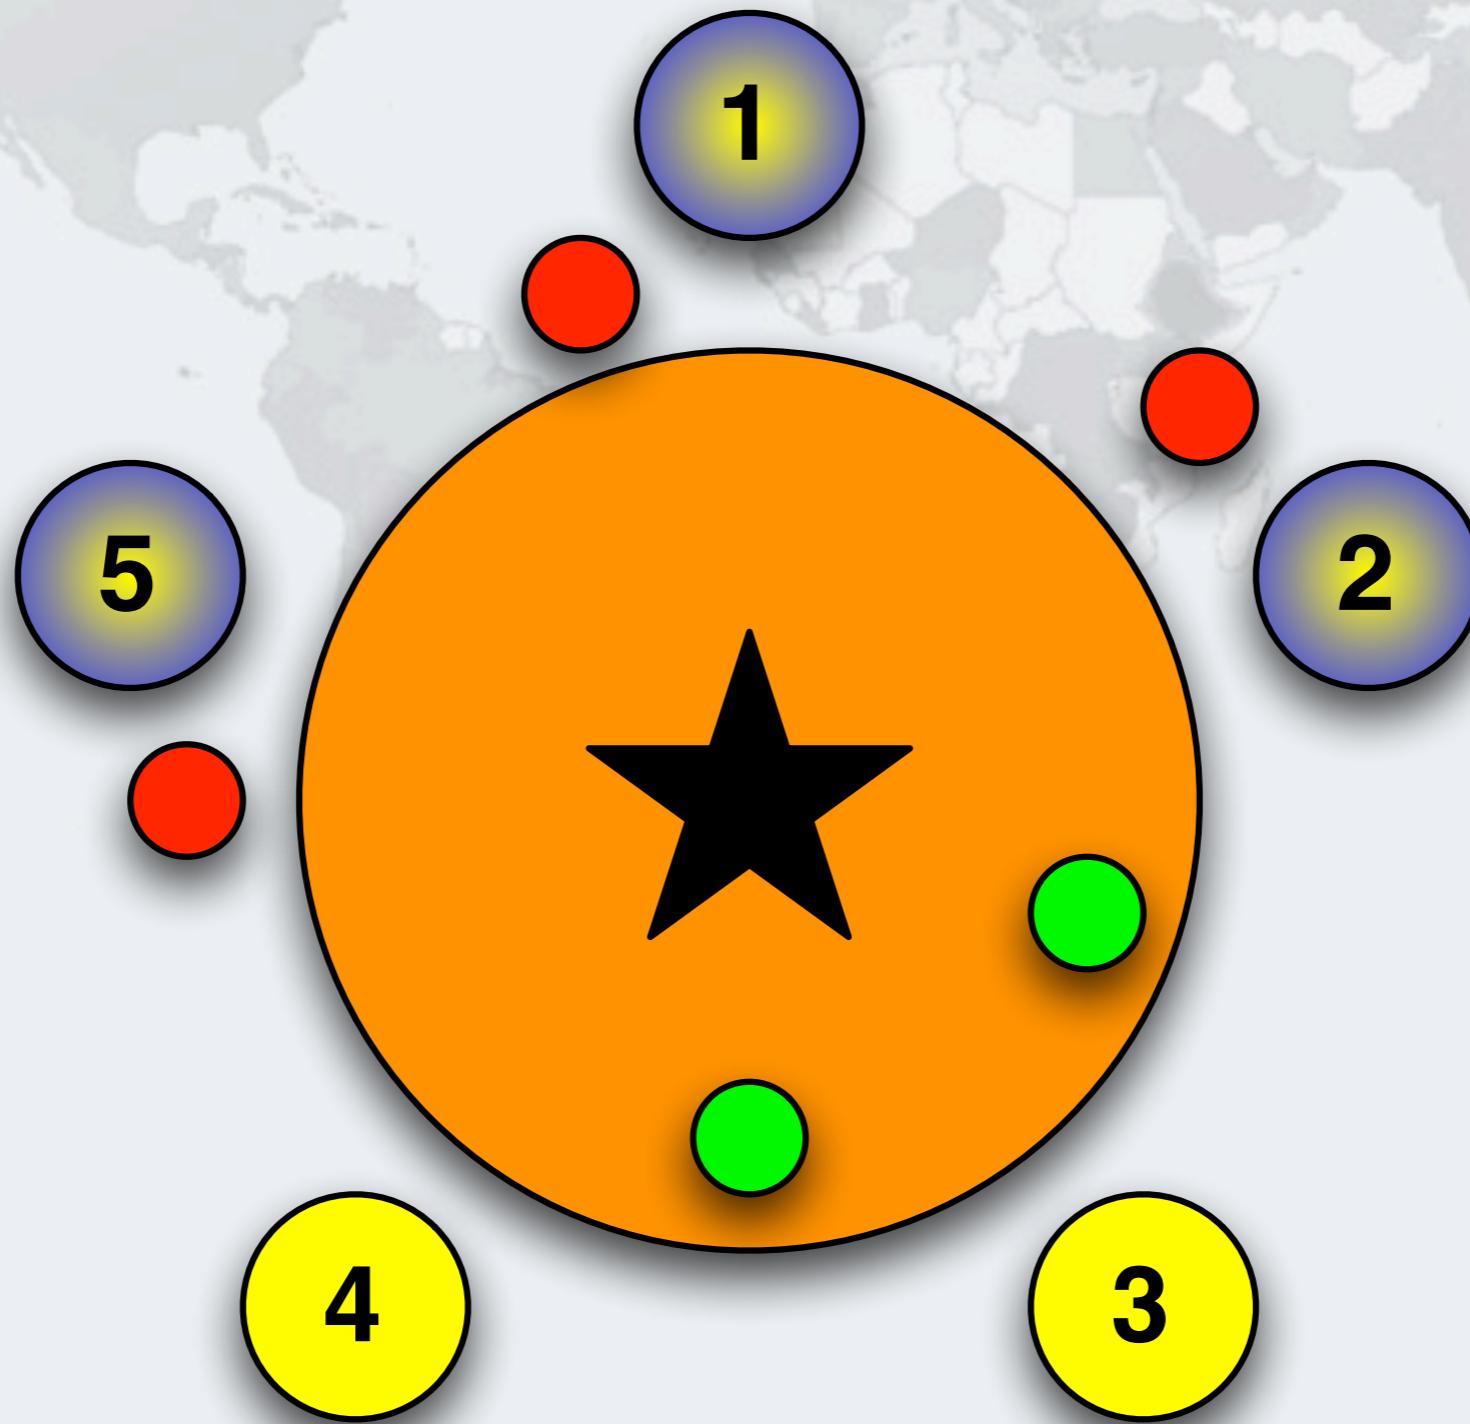

# Philosopher 5 Wants To Drink, Takes Right Cup

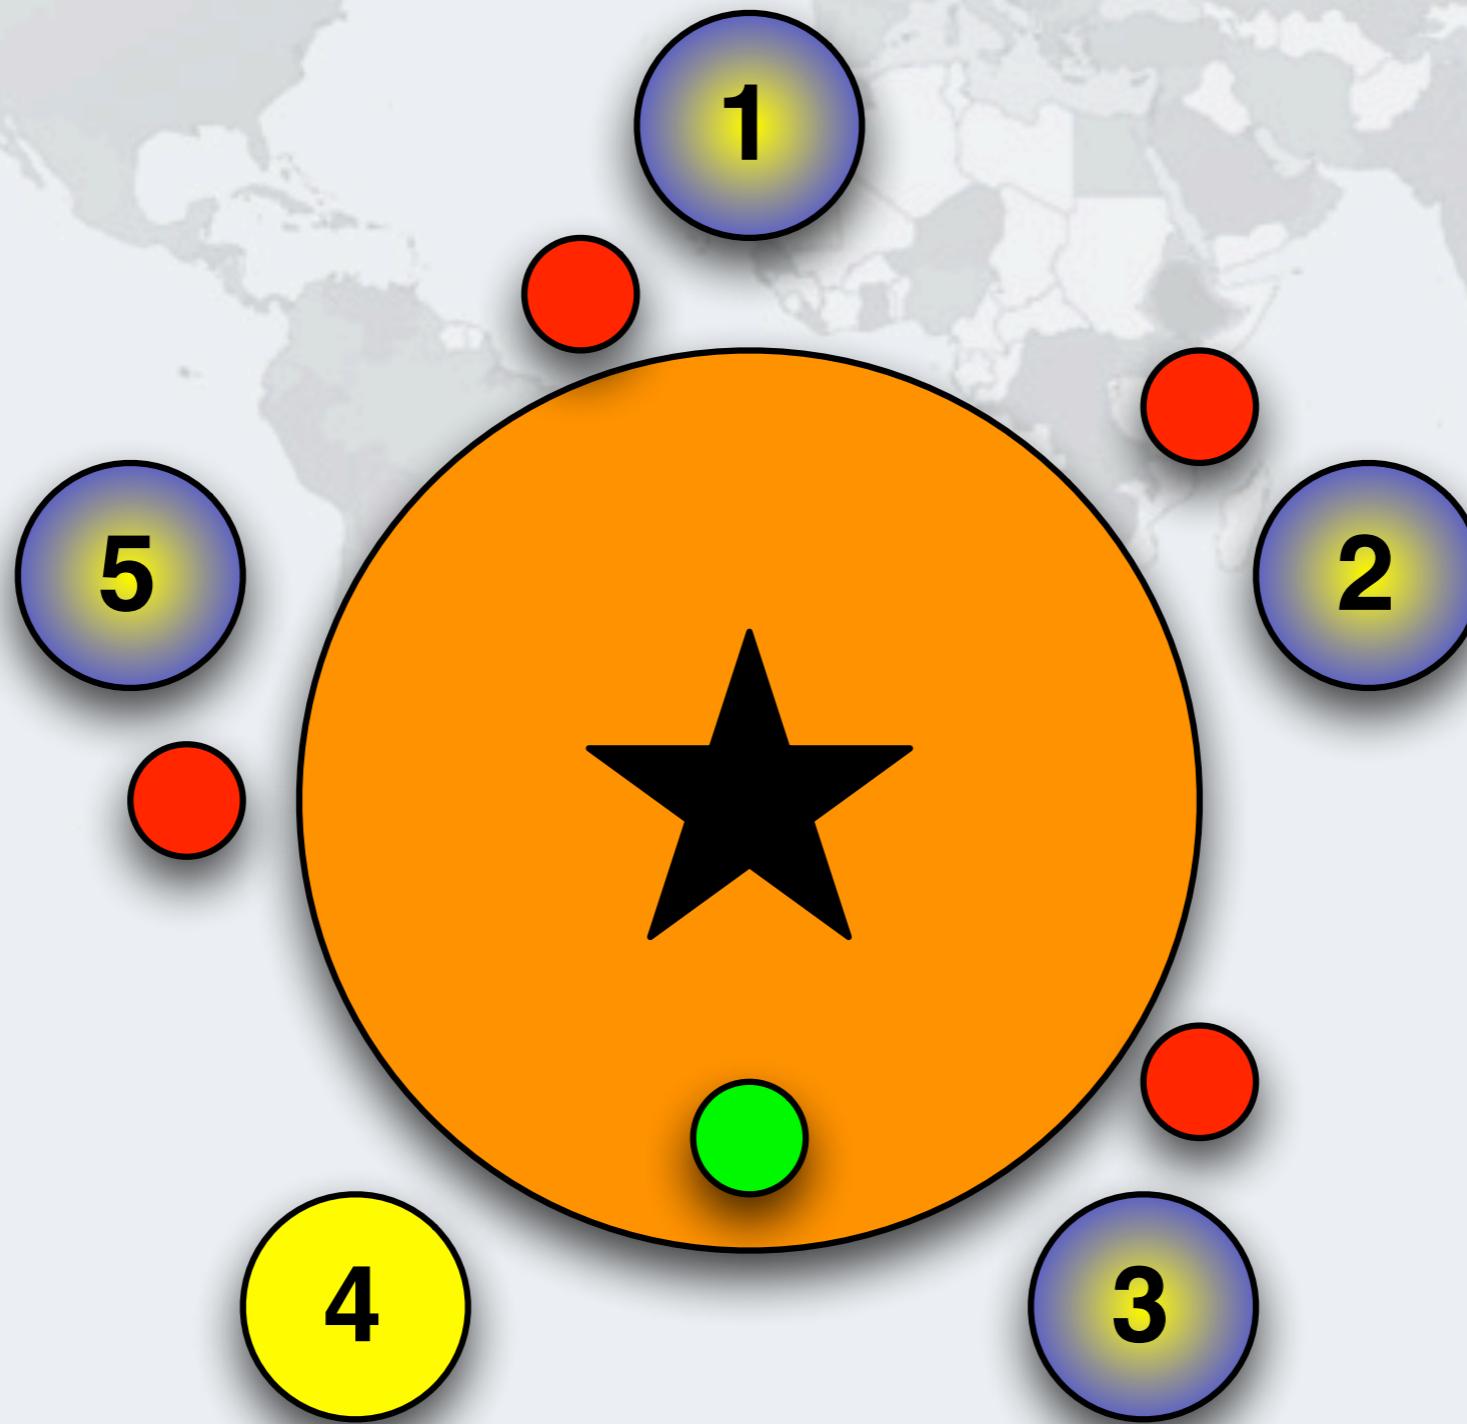

# Philosopher 1 Wants To Drink, Takes Right Cup

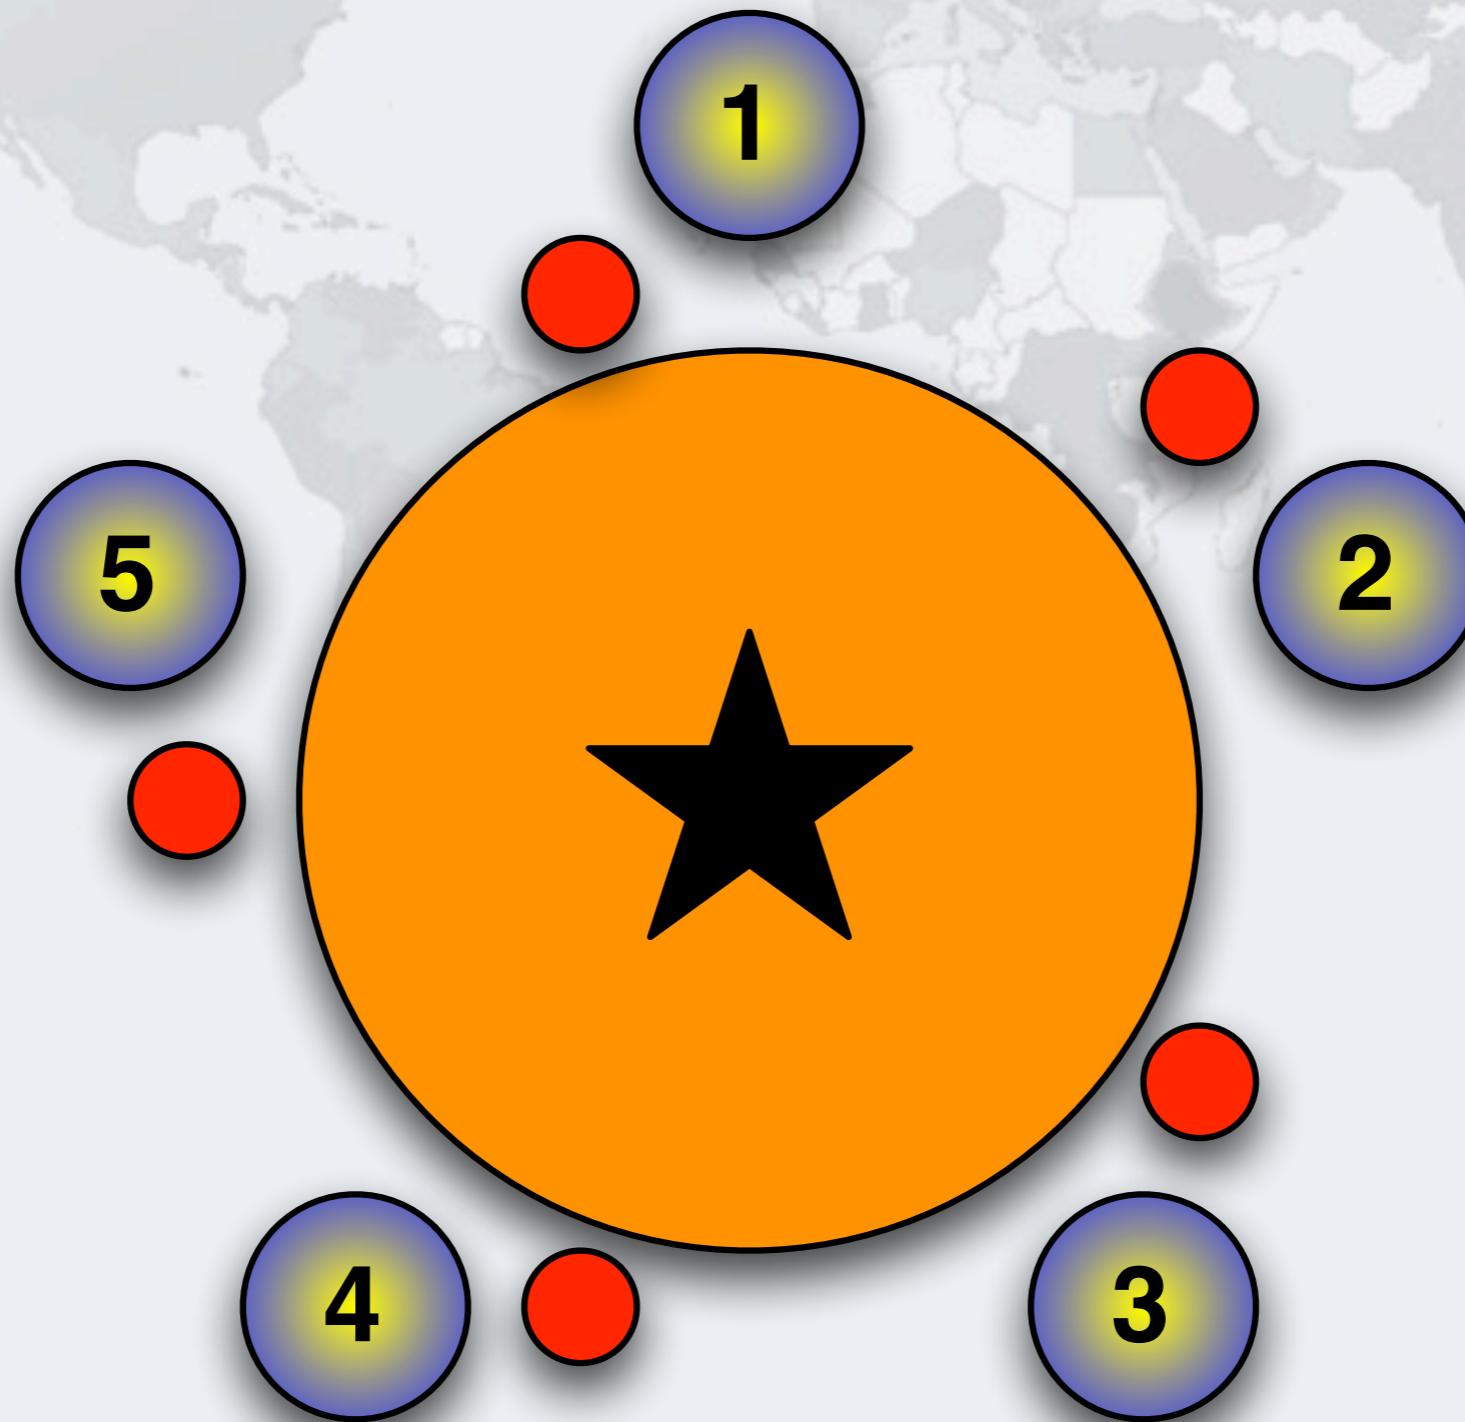

# Philosopher 2 Wants To Drink, Takes Right Cup

# Philosopher 3 Wants To Drink, Takes Right Cup

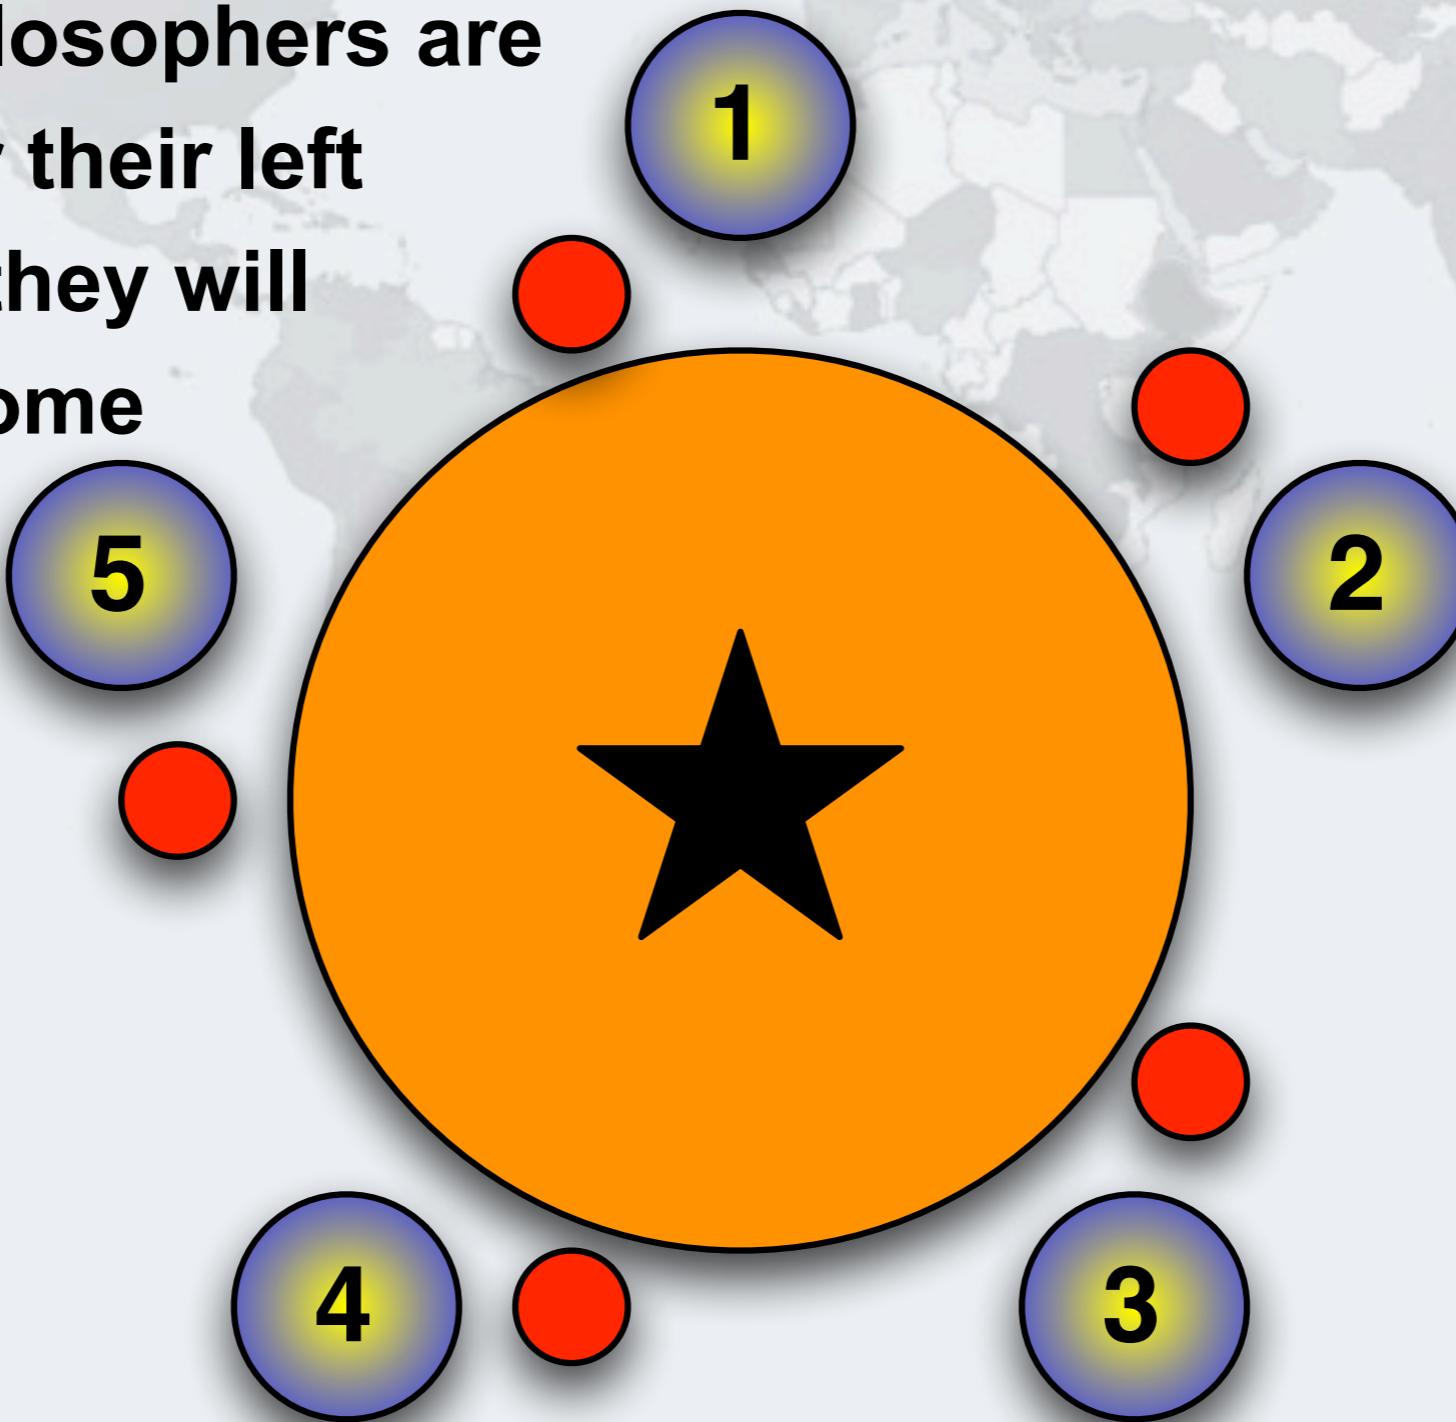

# Philosopher 4 Wants To Drink, Takes Right Cup

# Deadlock!

- All the philosophers are waiting for their left cups, but they will never become available

# Resolving Deadlocks

- Deadlocks can be discovered automatically by searching the graph of call stacks, looking for circular dependencies
  - ThreadMXBean can find deadlocks for us, but cannot fix them
- In databases, the deadlock is resolved by one of the queries being aborted with an exception
  - The query could then be retried
- Java does not have this functionality
  - When we get a deadlock, there is no clean way to recover from it
  - Prevention is better than the cure

# How Do We Discover Deadlocks?

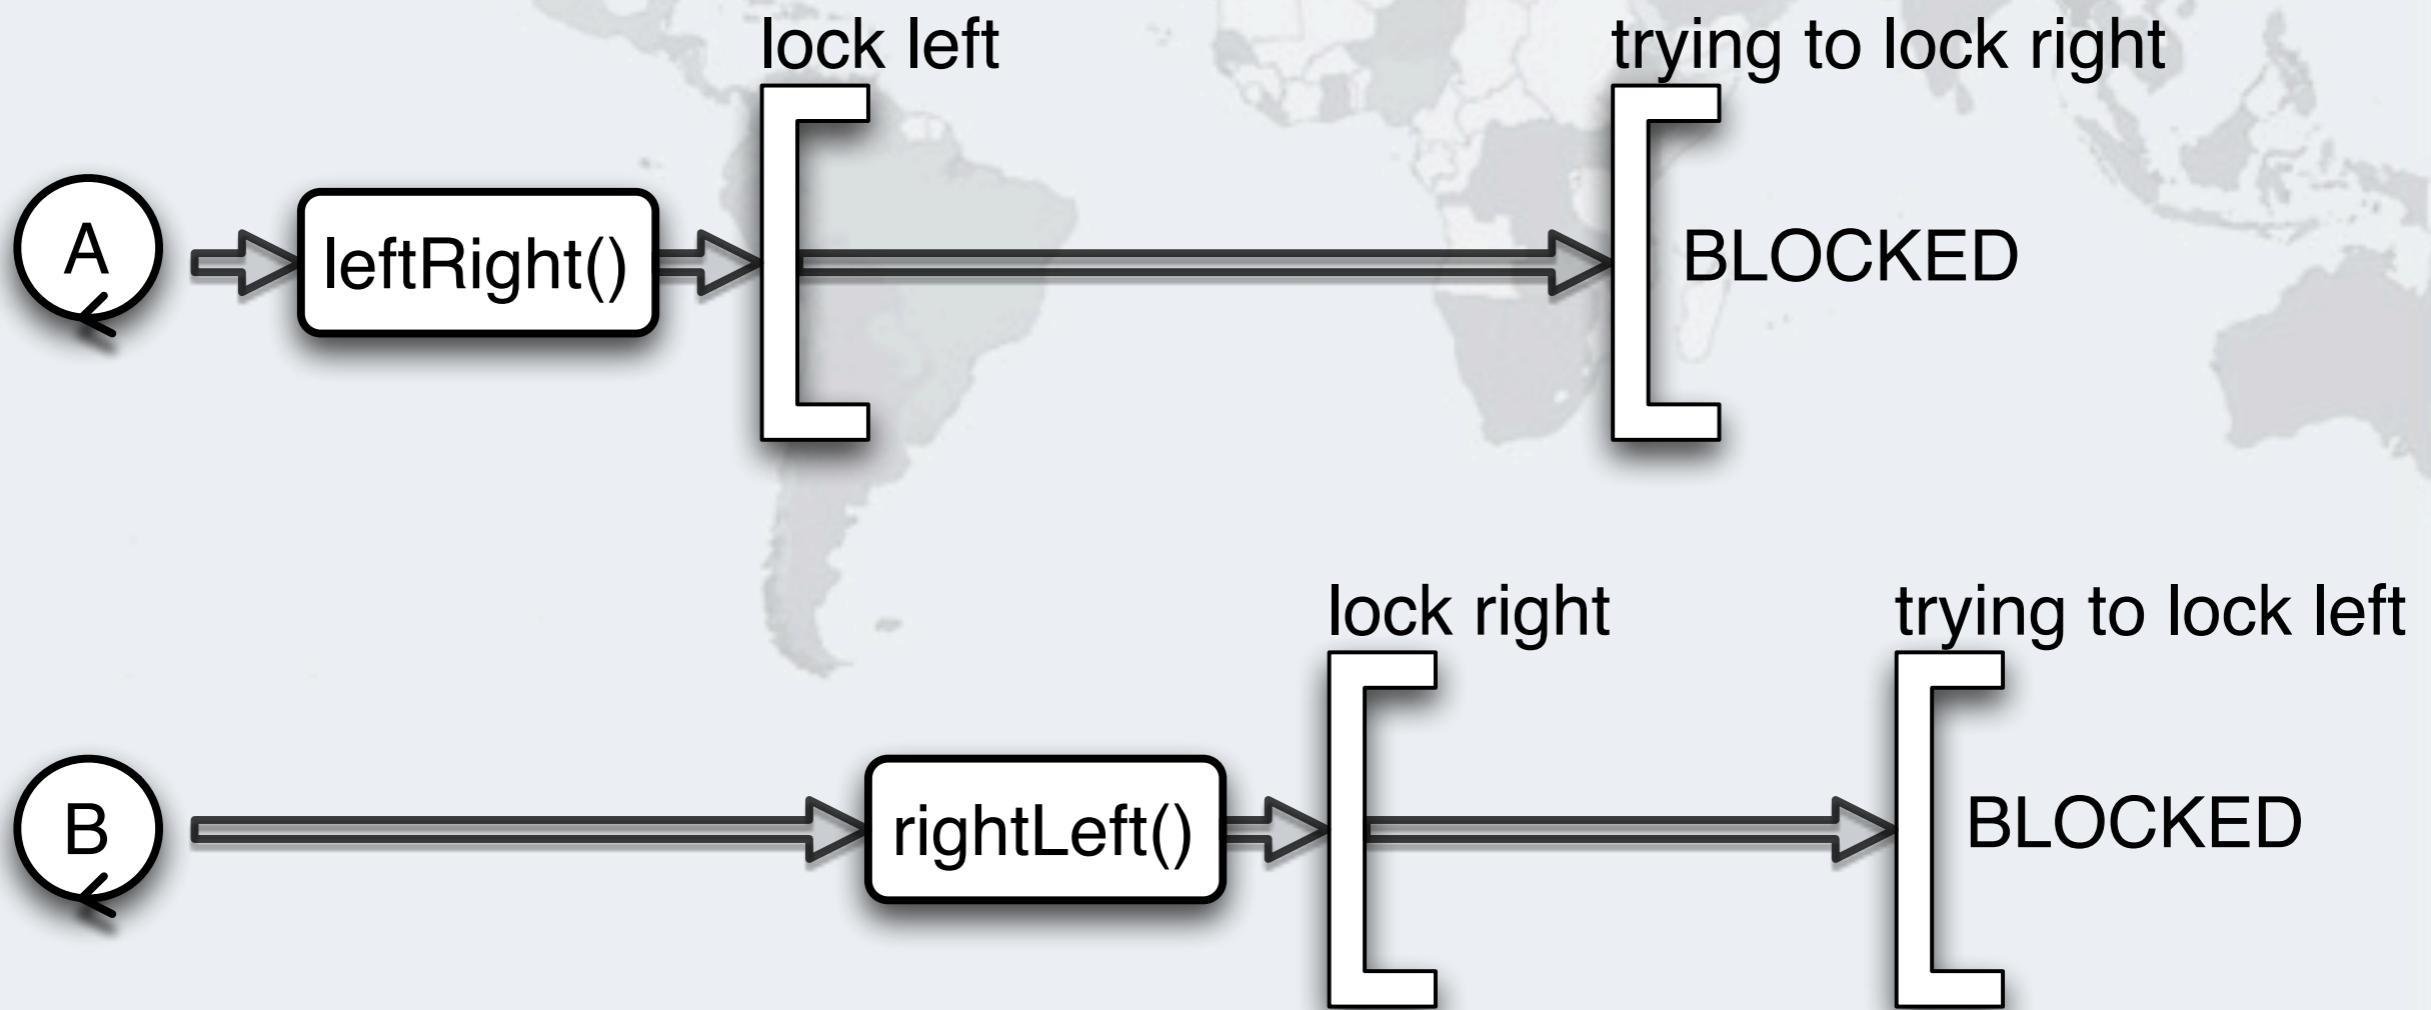

- A lot of Java code contains subtle locking bugs
  - Calling methods in different orders could cause a *deadly embrace*
  - Calling alien methods could cause a call-back
  - Limiting resources can cause deadlocks with dependent actions
- Most of the time, deadlocks do not manifest themselves
  - Usually never during testing
  - Seldom during production, only if the system is really busy
    - Often you will need to run the application for 5 days before it happens, usually on a Friday afternoon to ruin your weekend

# Lock-ordering Deadlocks

- This code will cause deadlocks if called by two threads

```
public class LeftRightDeadlock {  
    private final Object left = new Object();  
    private final Object right = new Object();  
    public void leftRight() {  
        synchronized (left) {  
            synchronized (right) {  
                doSomething();  
            }  
        }  
    }  
    public void rightLeft() {  
        synchronized (right) {  
            synchronized (left) {  
                doSomethingElse();  
            }  
        }  
    }  
}
```

# Interleaving Of Call Sequence Causes Deadlock

## Global Order Of Locks

- A program will be free of lock-ordering deadlocks if all threads acquire the locks they need in a *fixed global order*
  - Thus we can solve the deadlock by changing rightLeft() to

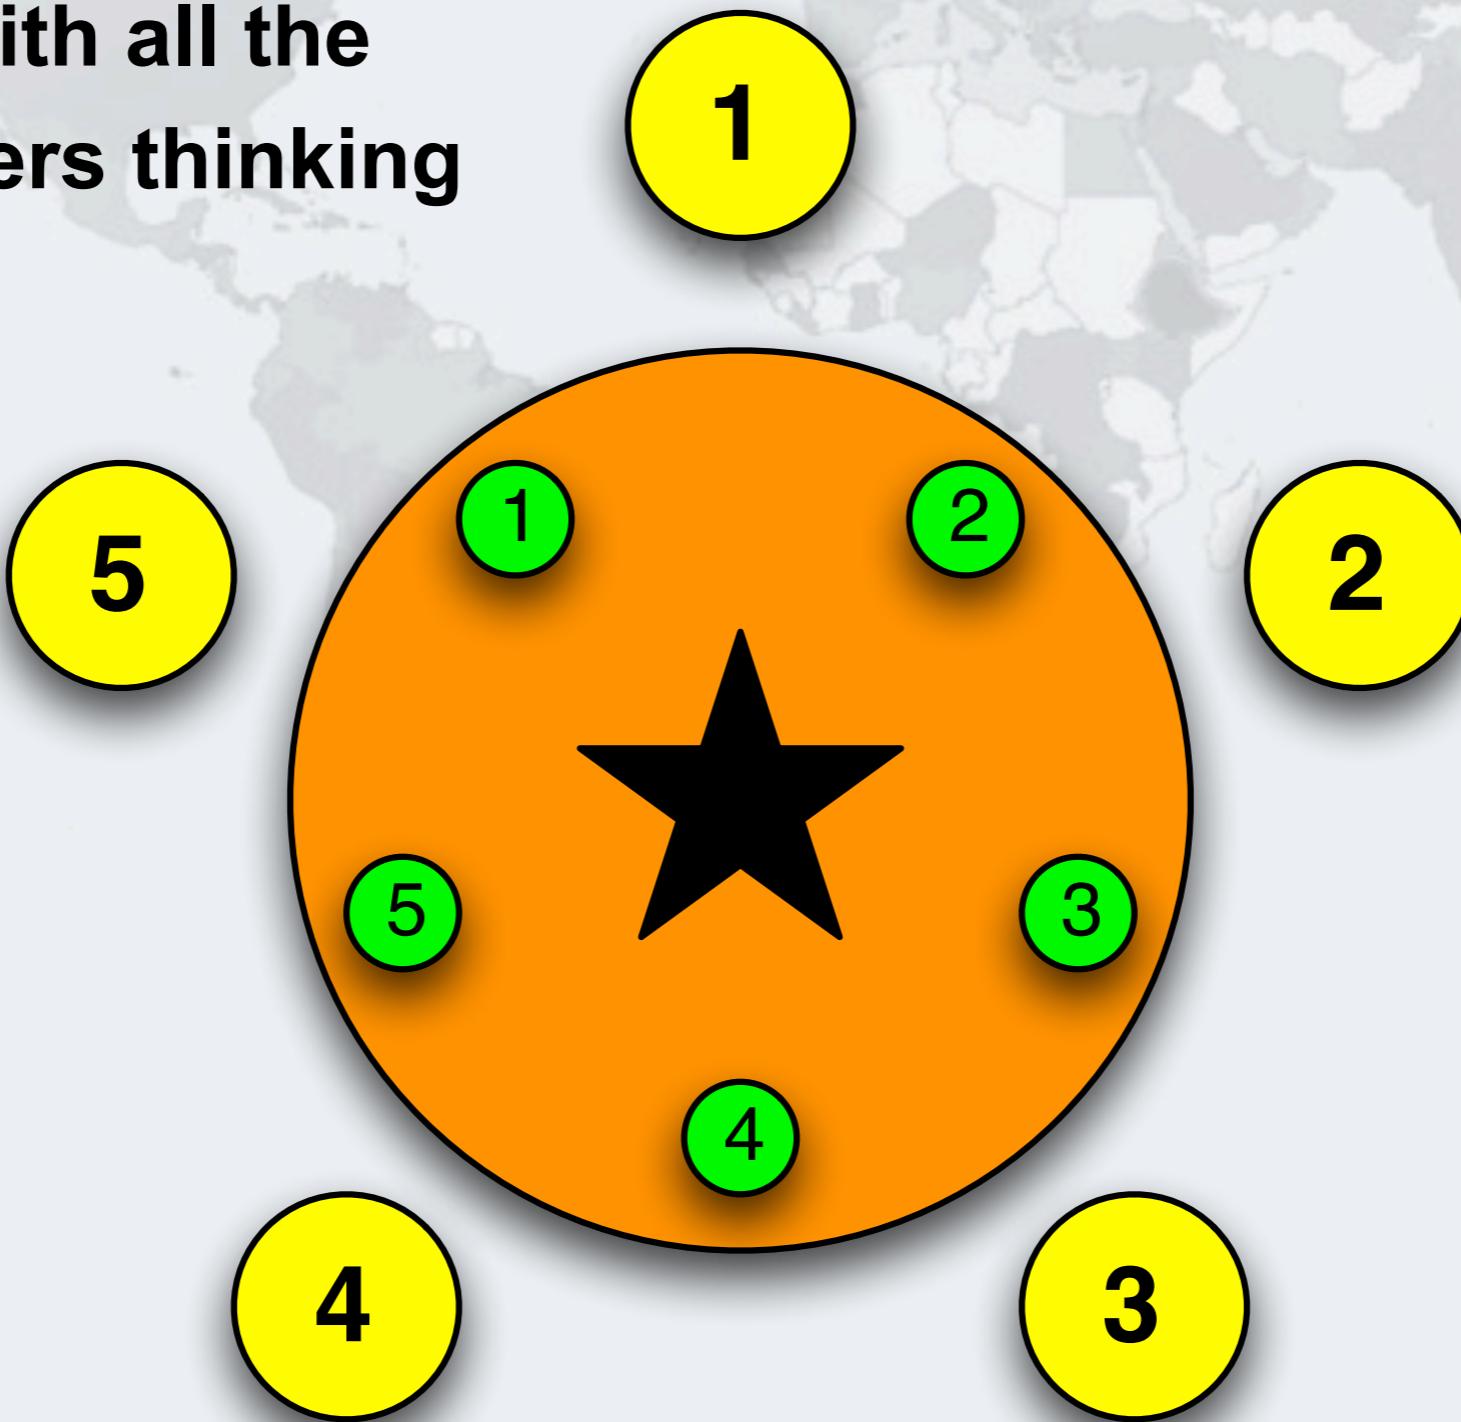

```
public void rightLeft() {  
    synchronized (left) {  
        synchronized (right) {  
            doSomethingElse();  
        }  
    }  
}
```

# Global Order With Boozing Philosophers

- We can solve the deadlock with the "dining philosophers" by requiring that locks are always acquired in a set order
  - For example, we can make a rule that philosophers always first take the cup with the largest number
  - And return the cup with the lowest number first

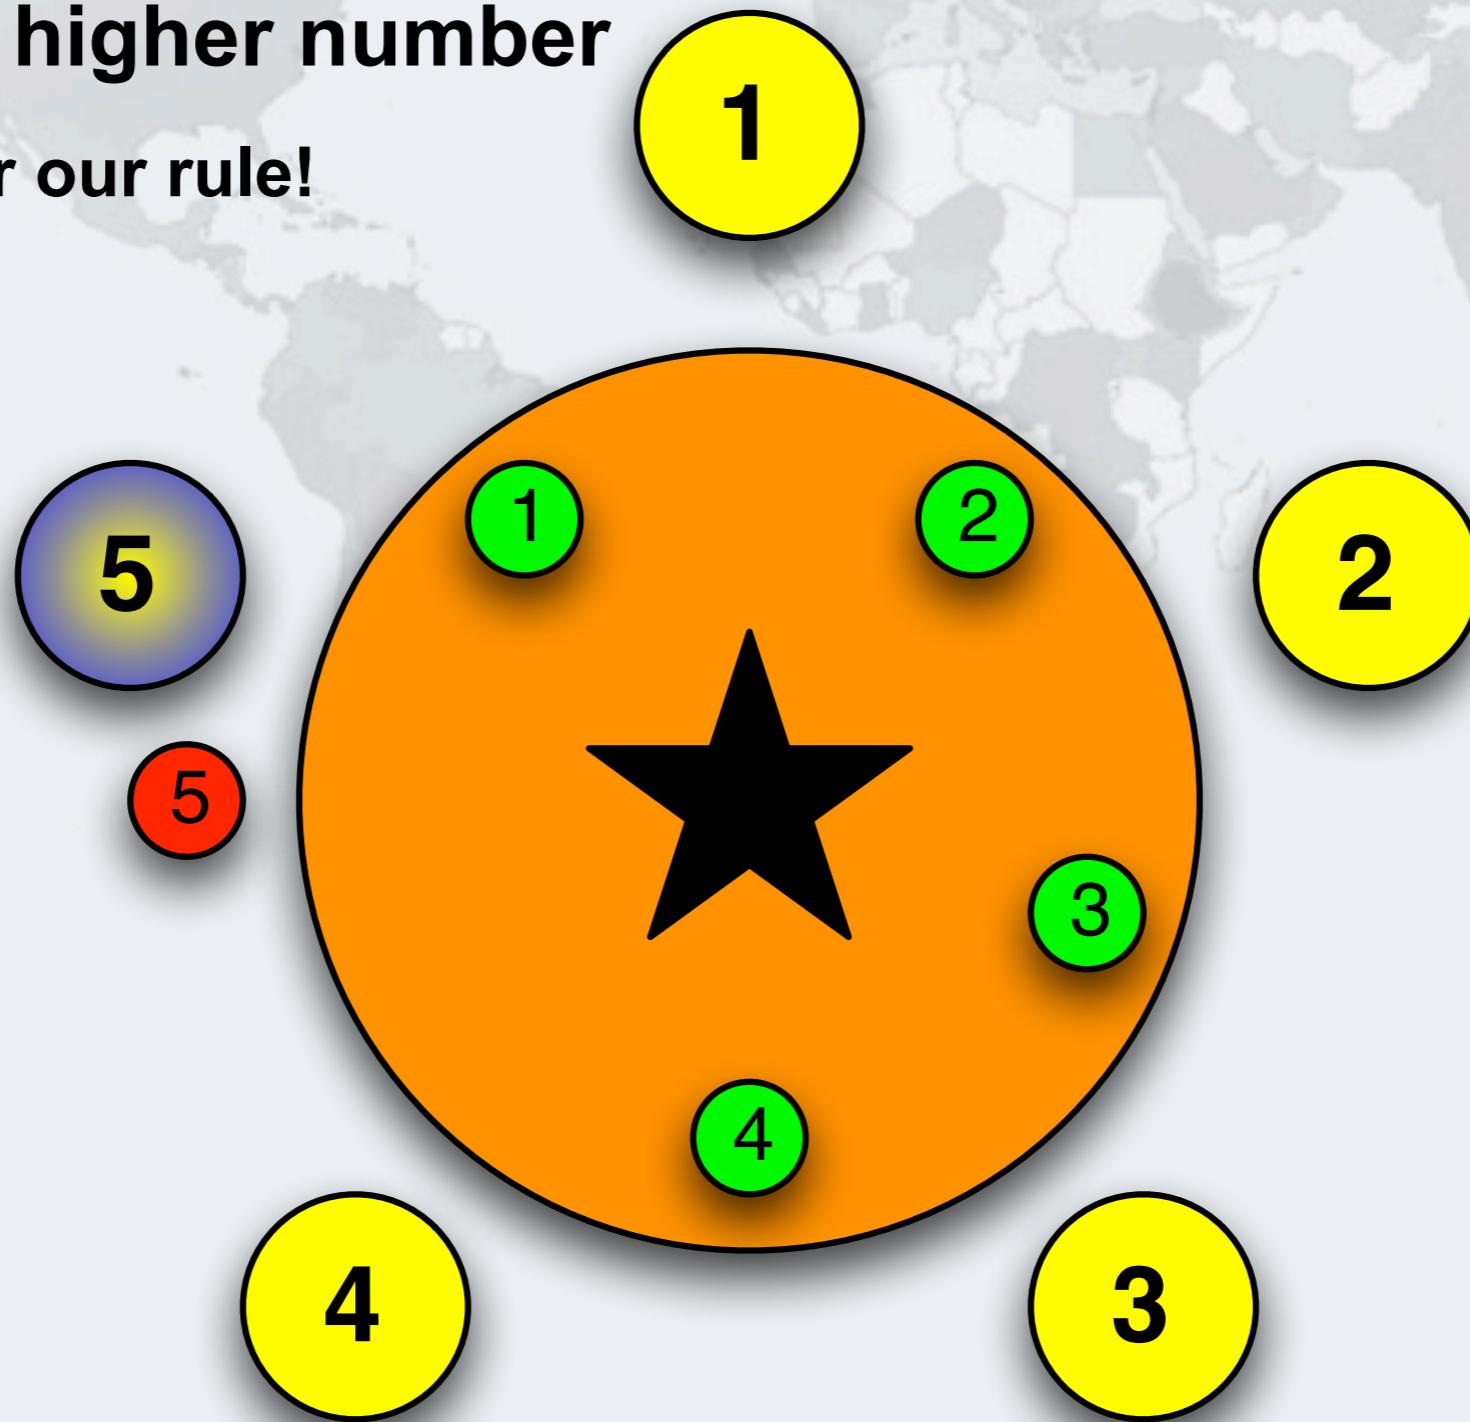

# Global Lock Ordering

- We start with all the philosophers thinking

## Philosopher 5 Takes Cup 5

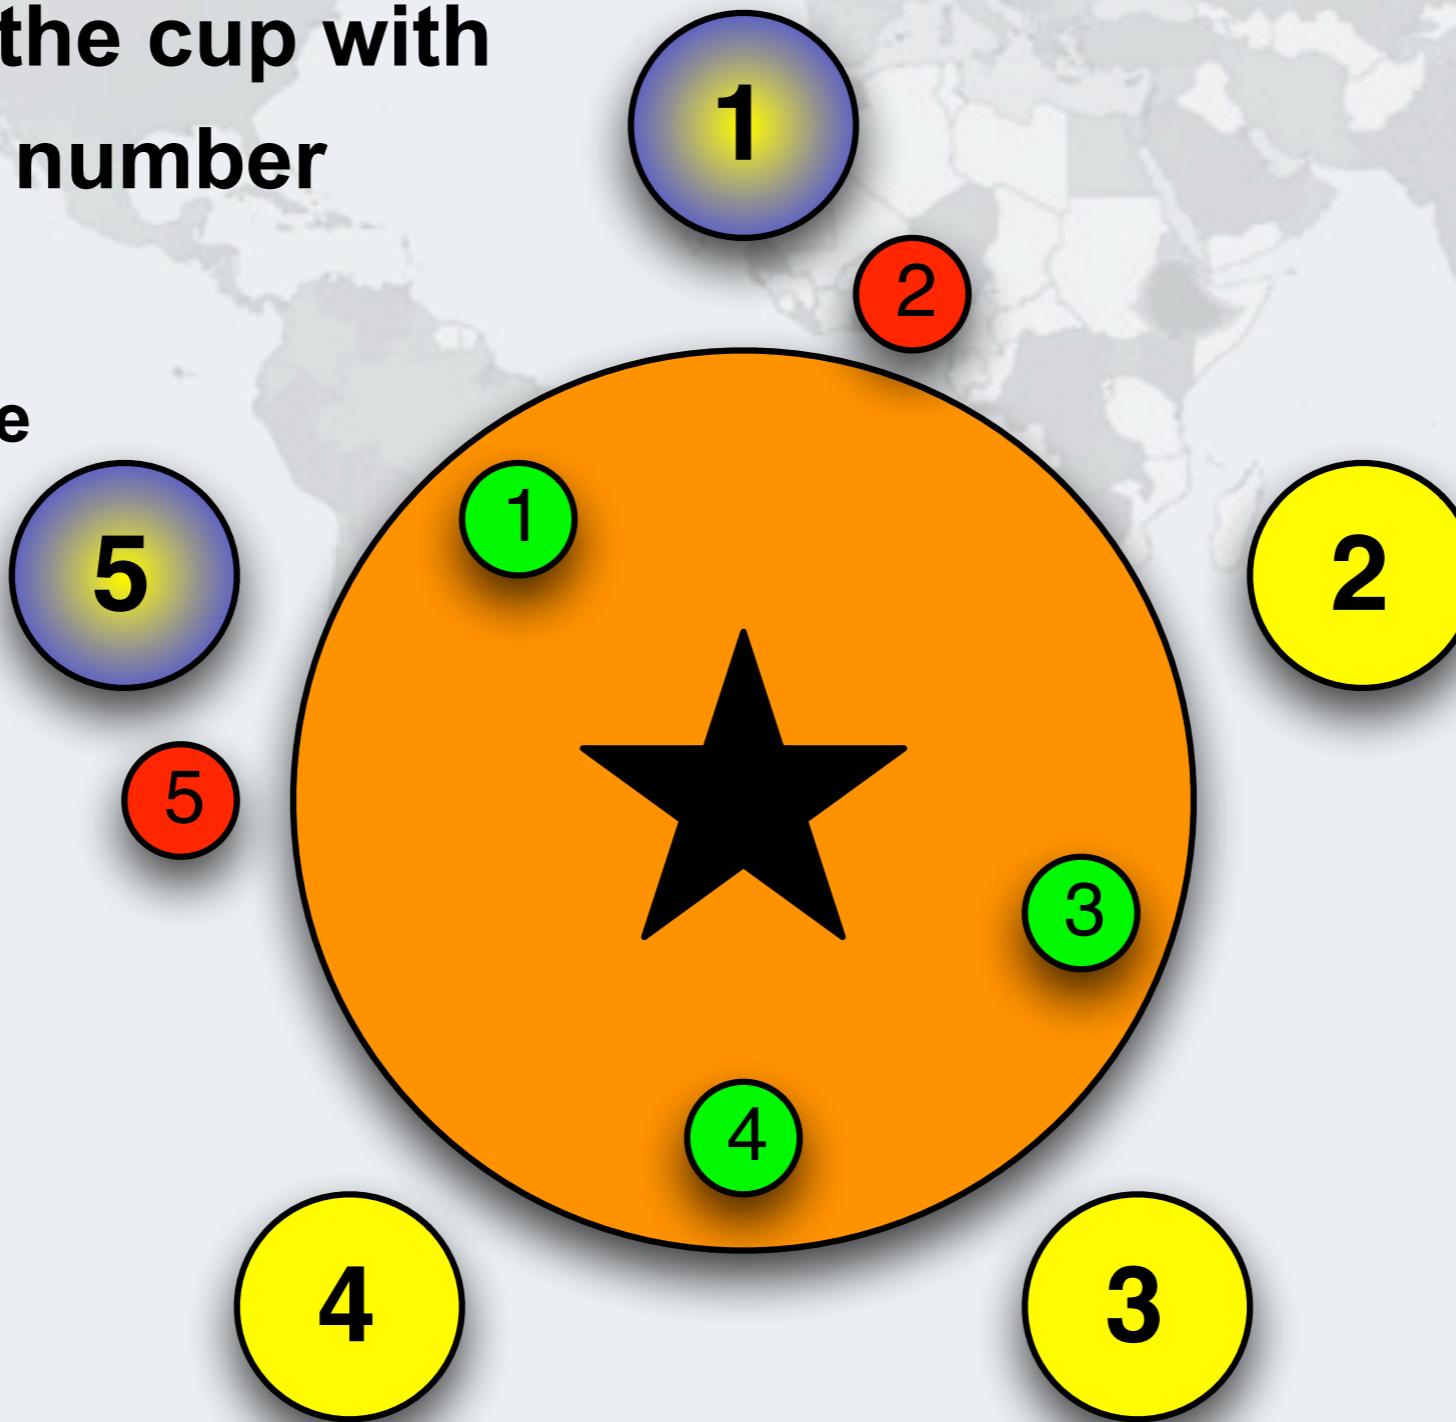

- Cup 5 has higher number
  - Remember our rule!

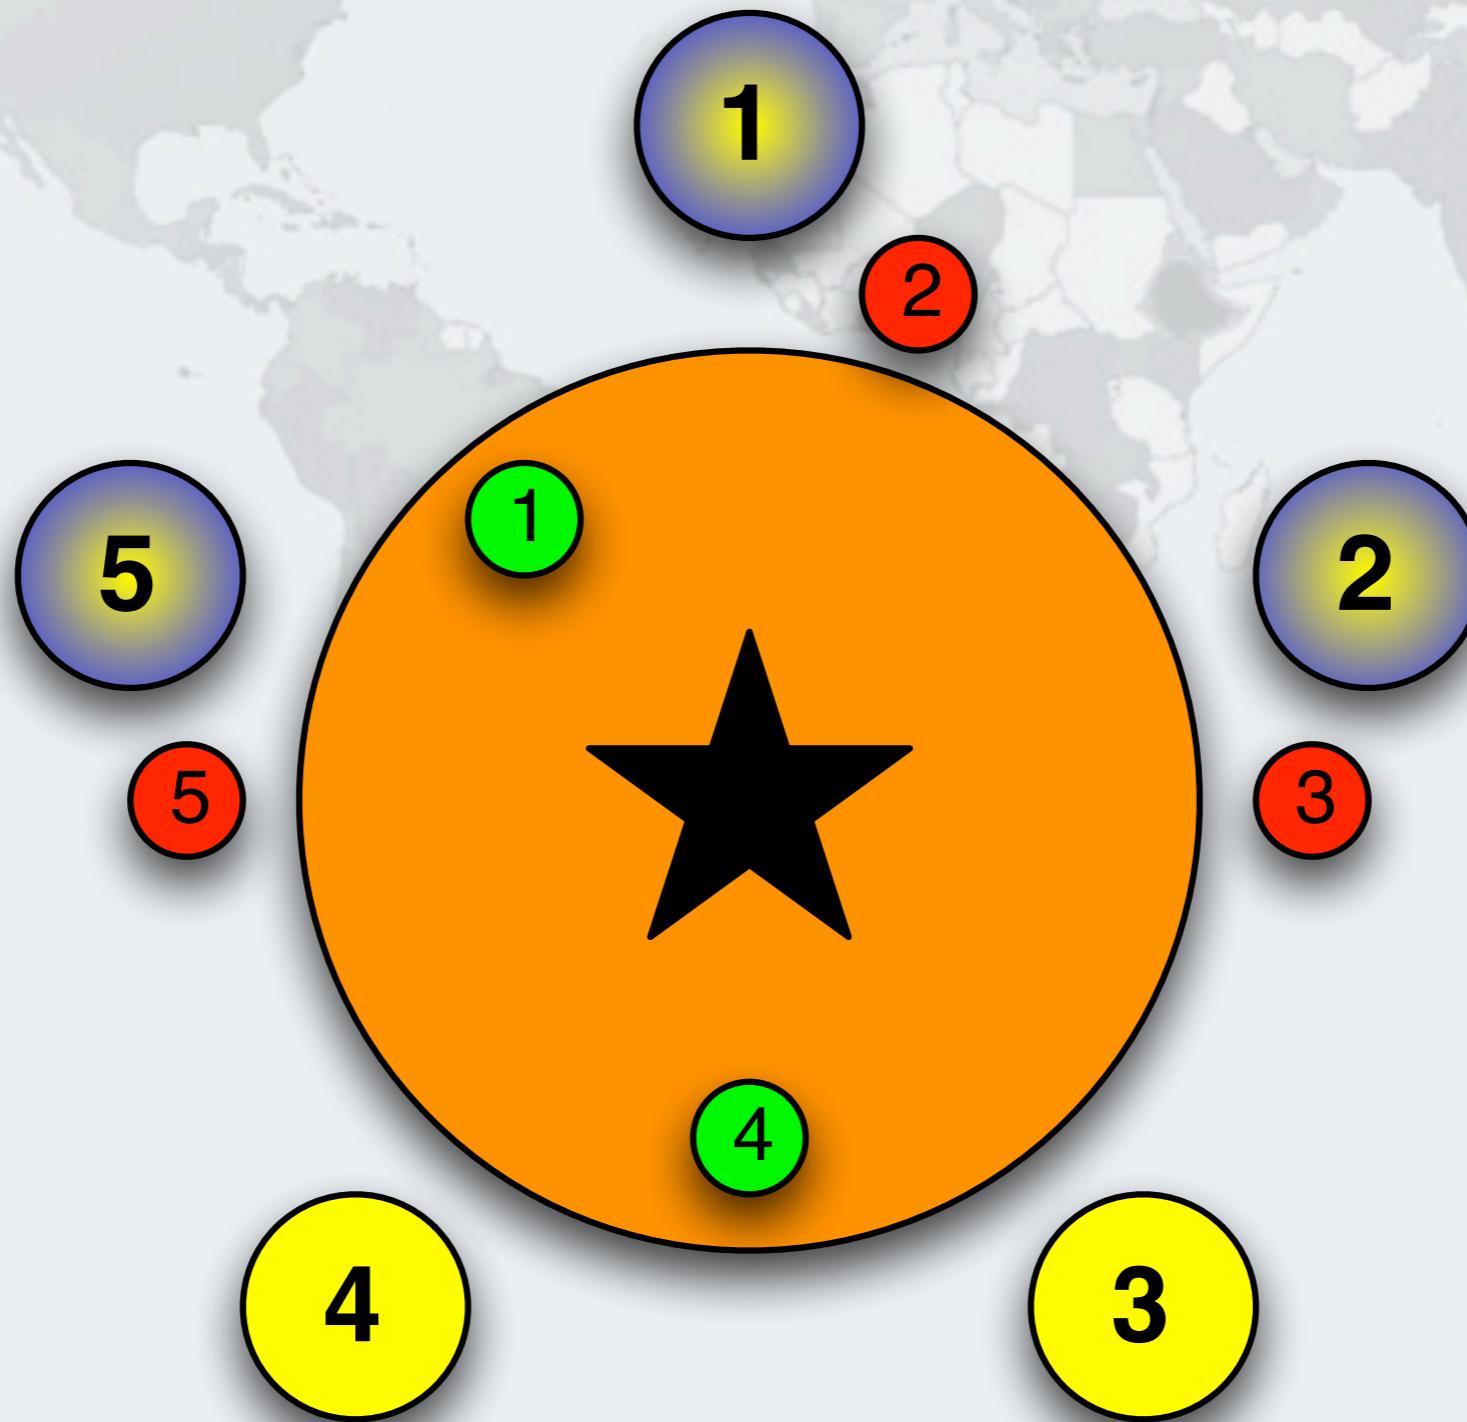

## Philosopher 1 Takes Cup 2

- Must take the cup with the higher number first

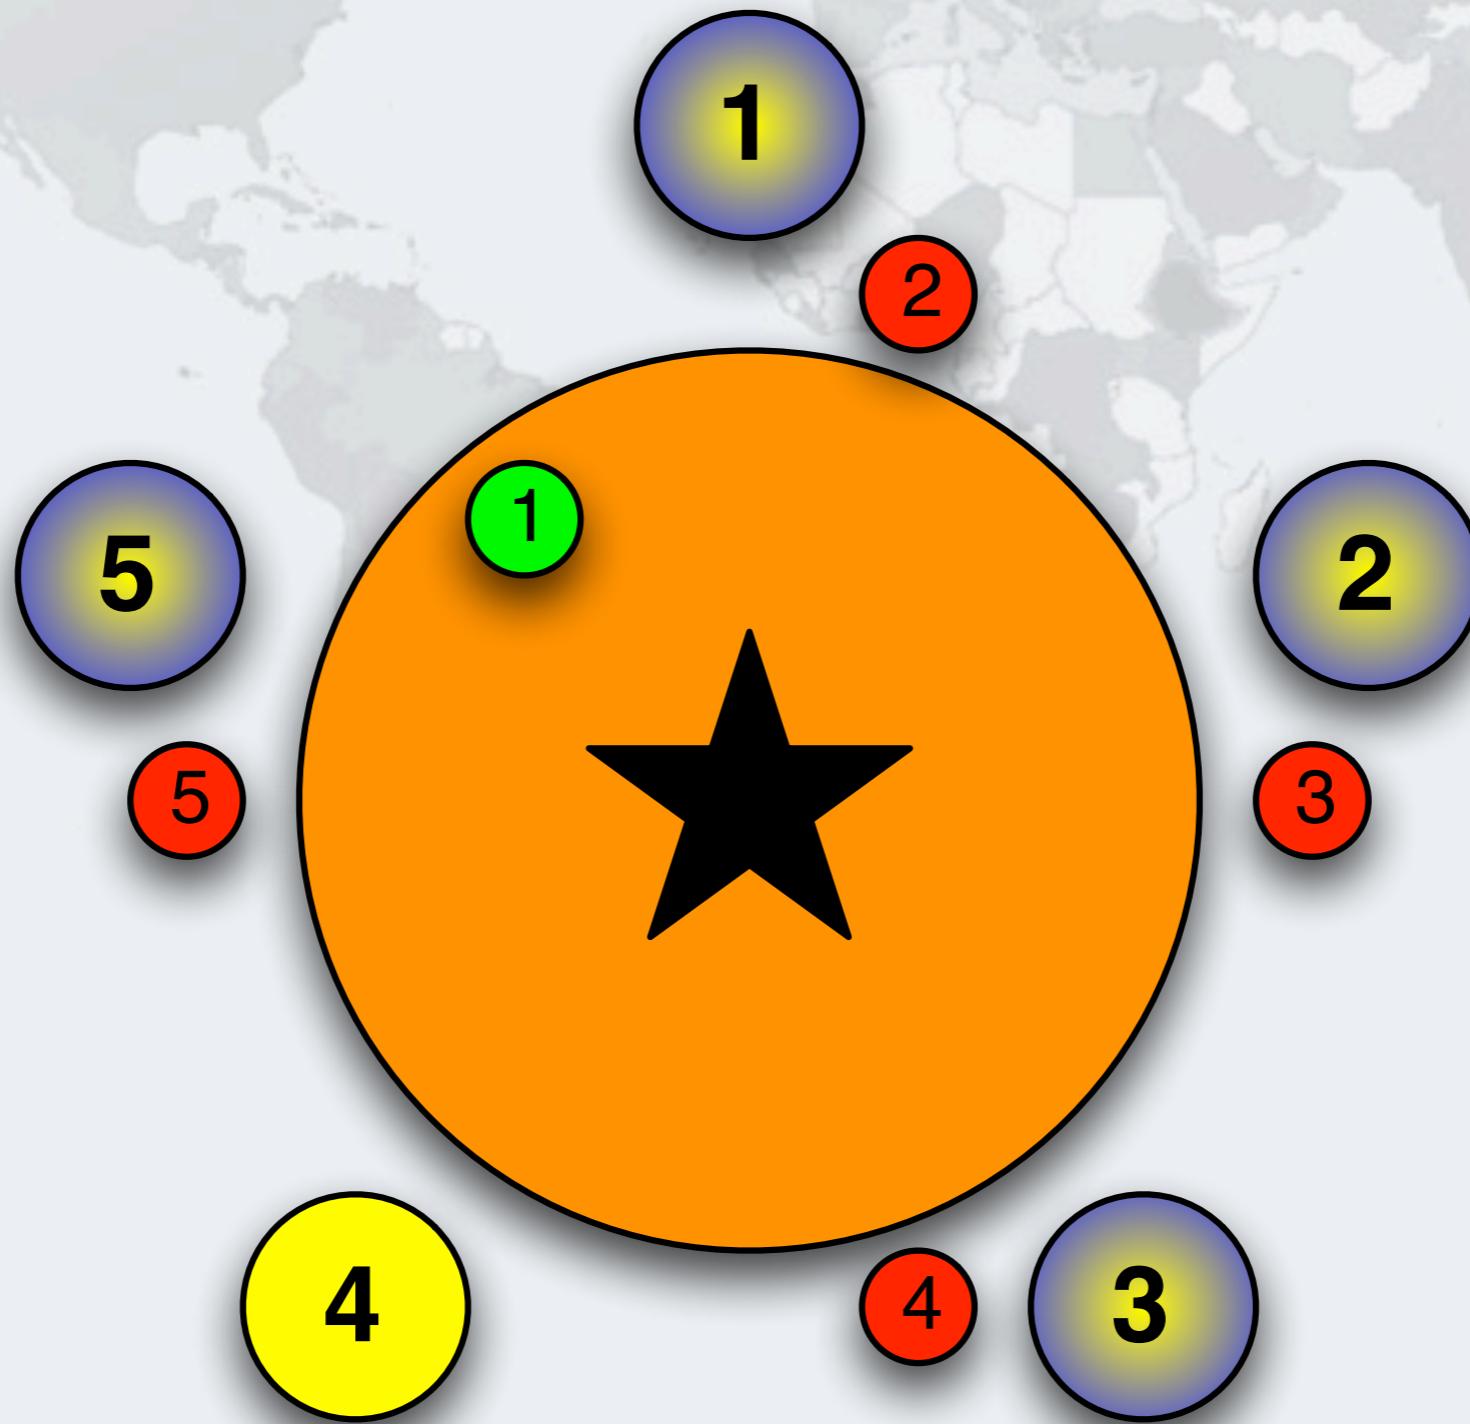

- In this case cup 2

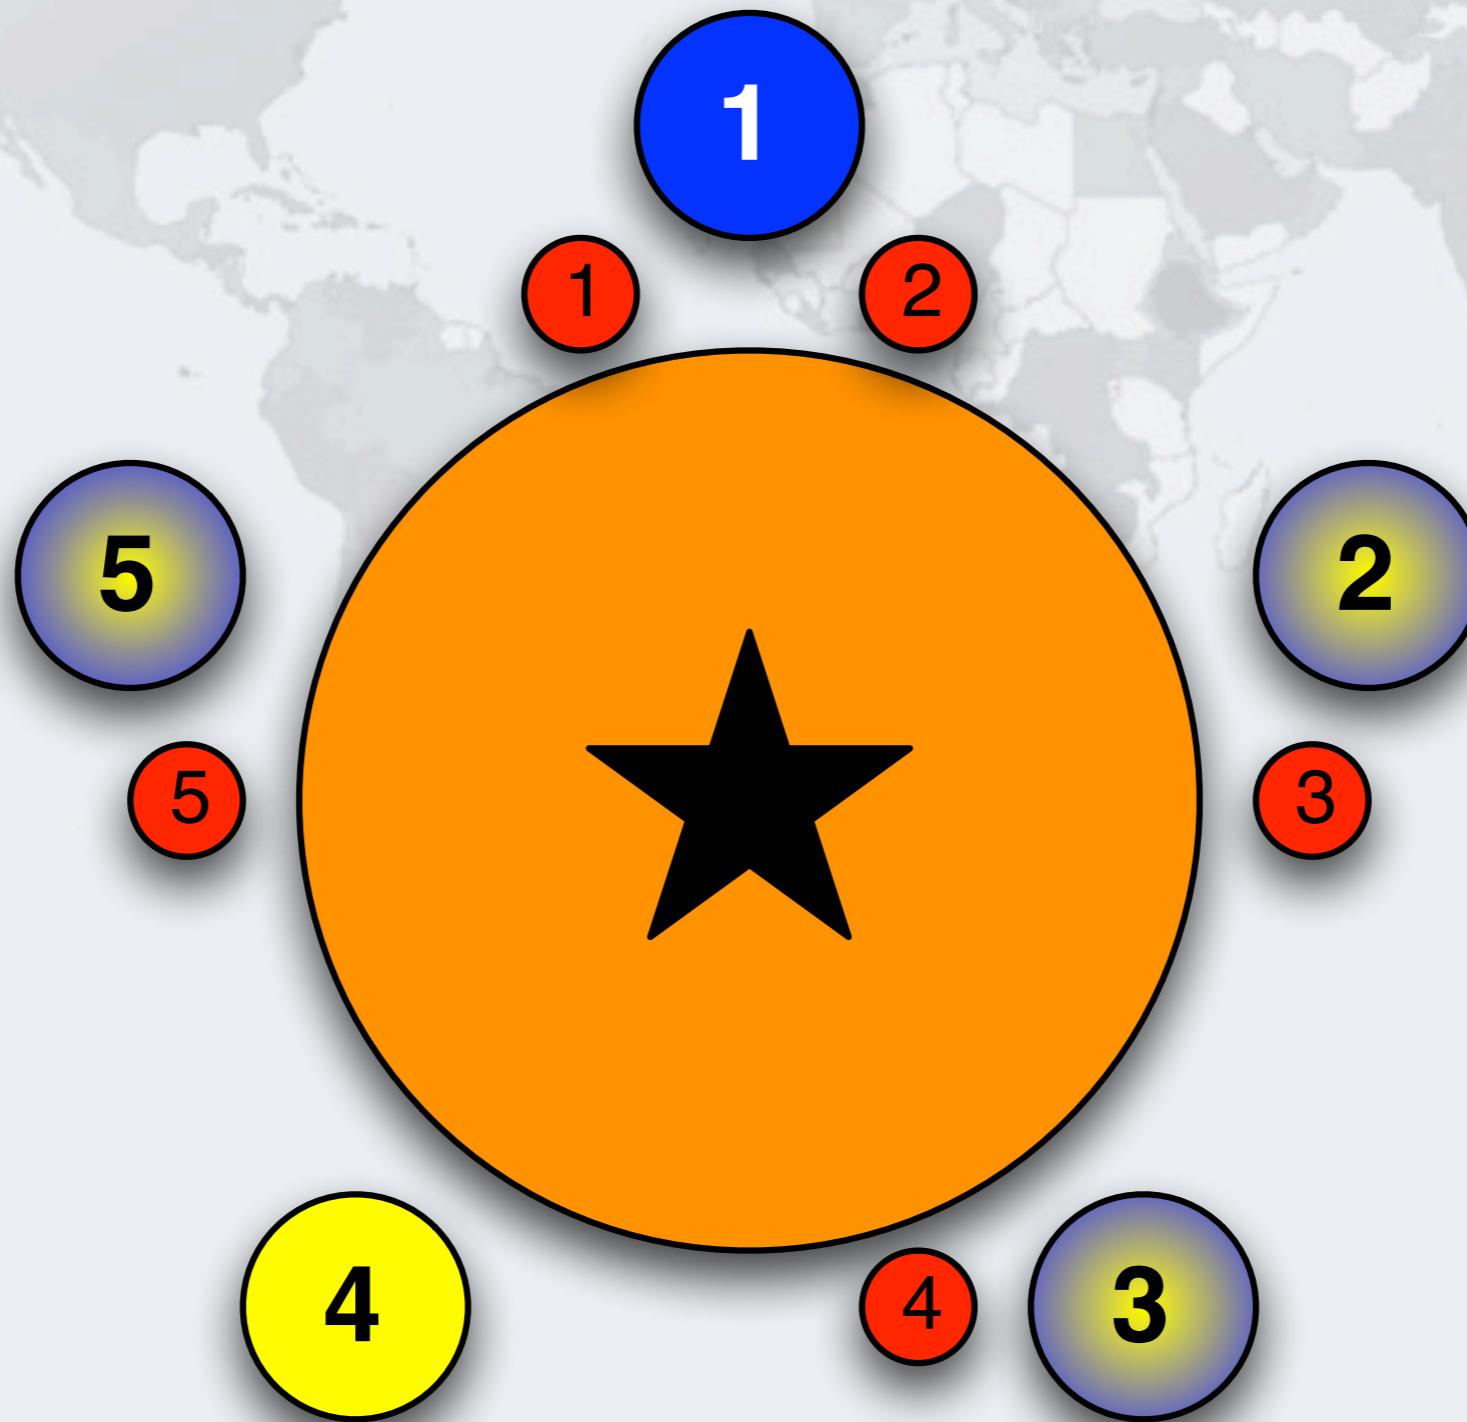

## Philosopher 2 Takes Cup 3

# Philosopher 3 Takes Cup 4

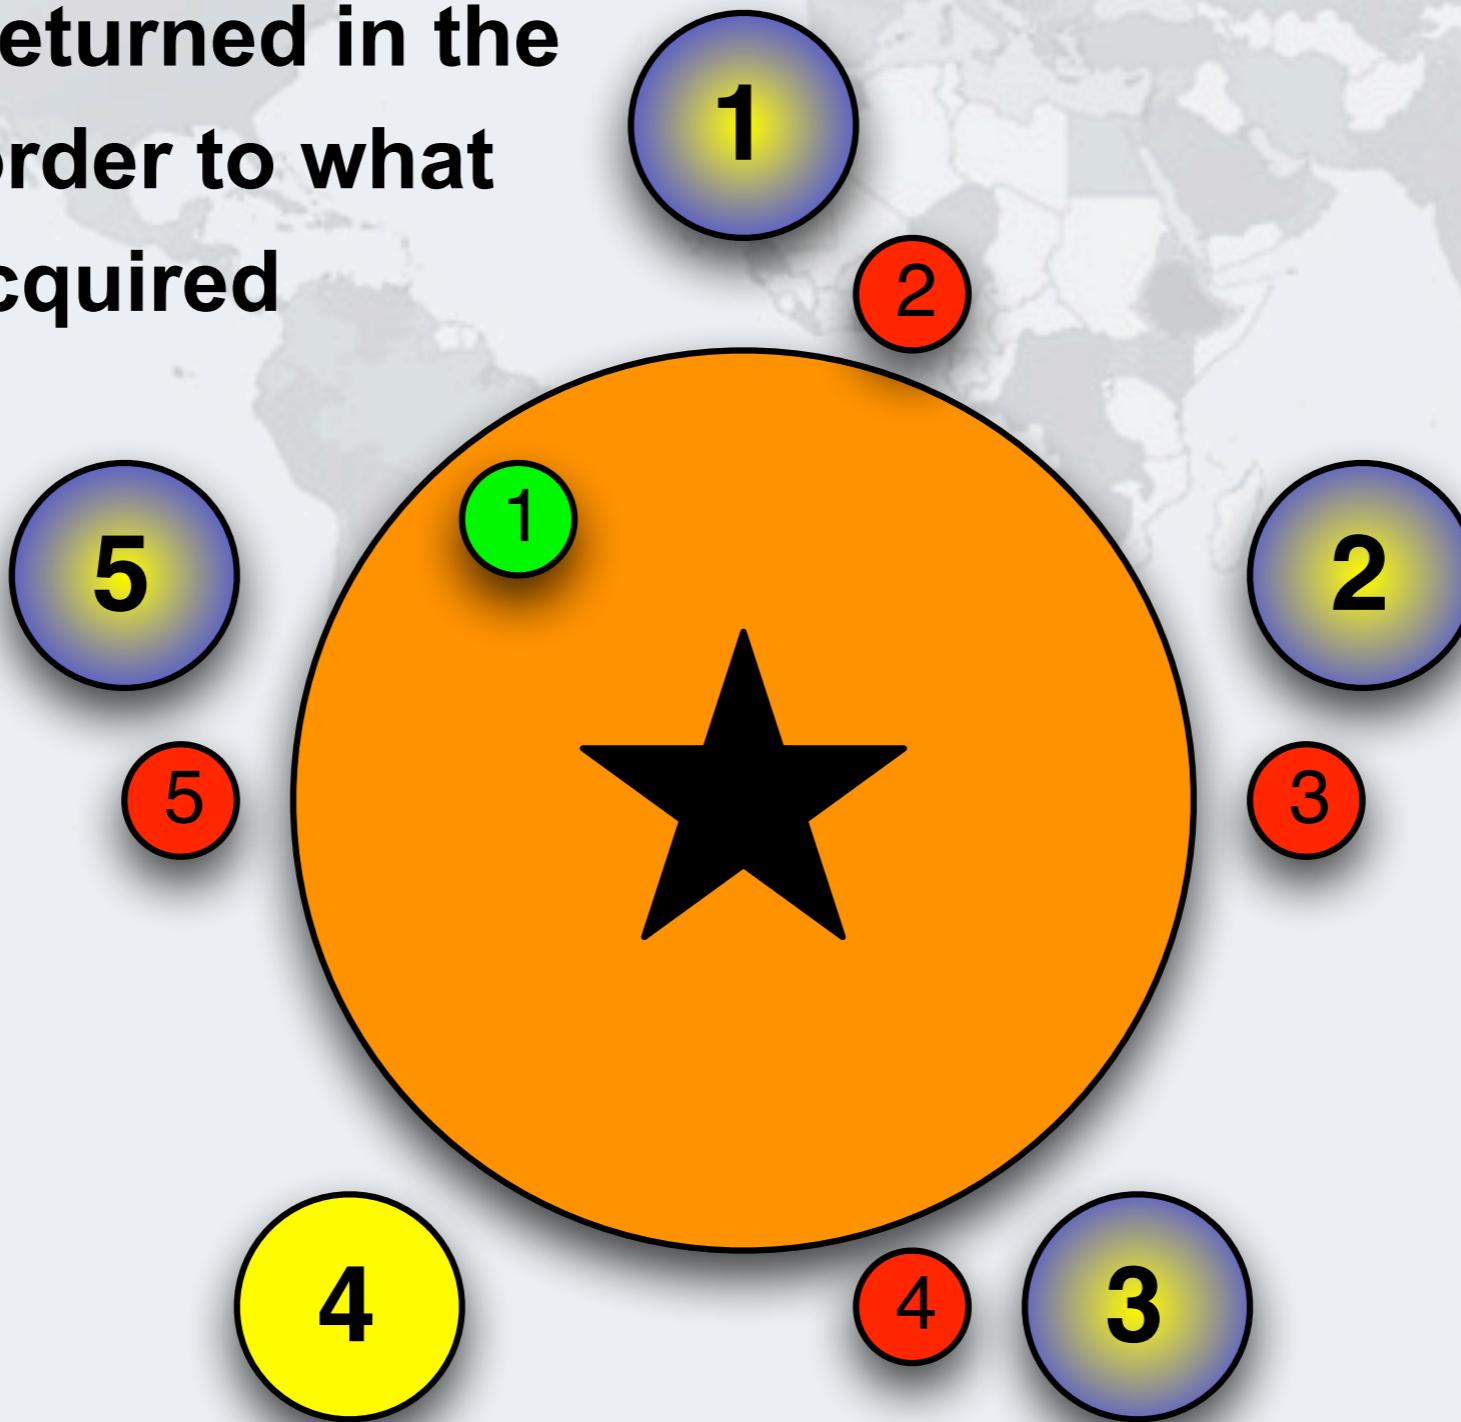

# Philosopher 1 Takes Cup 1 - Drinking

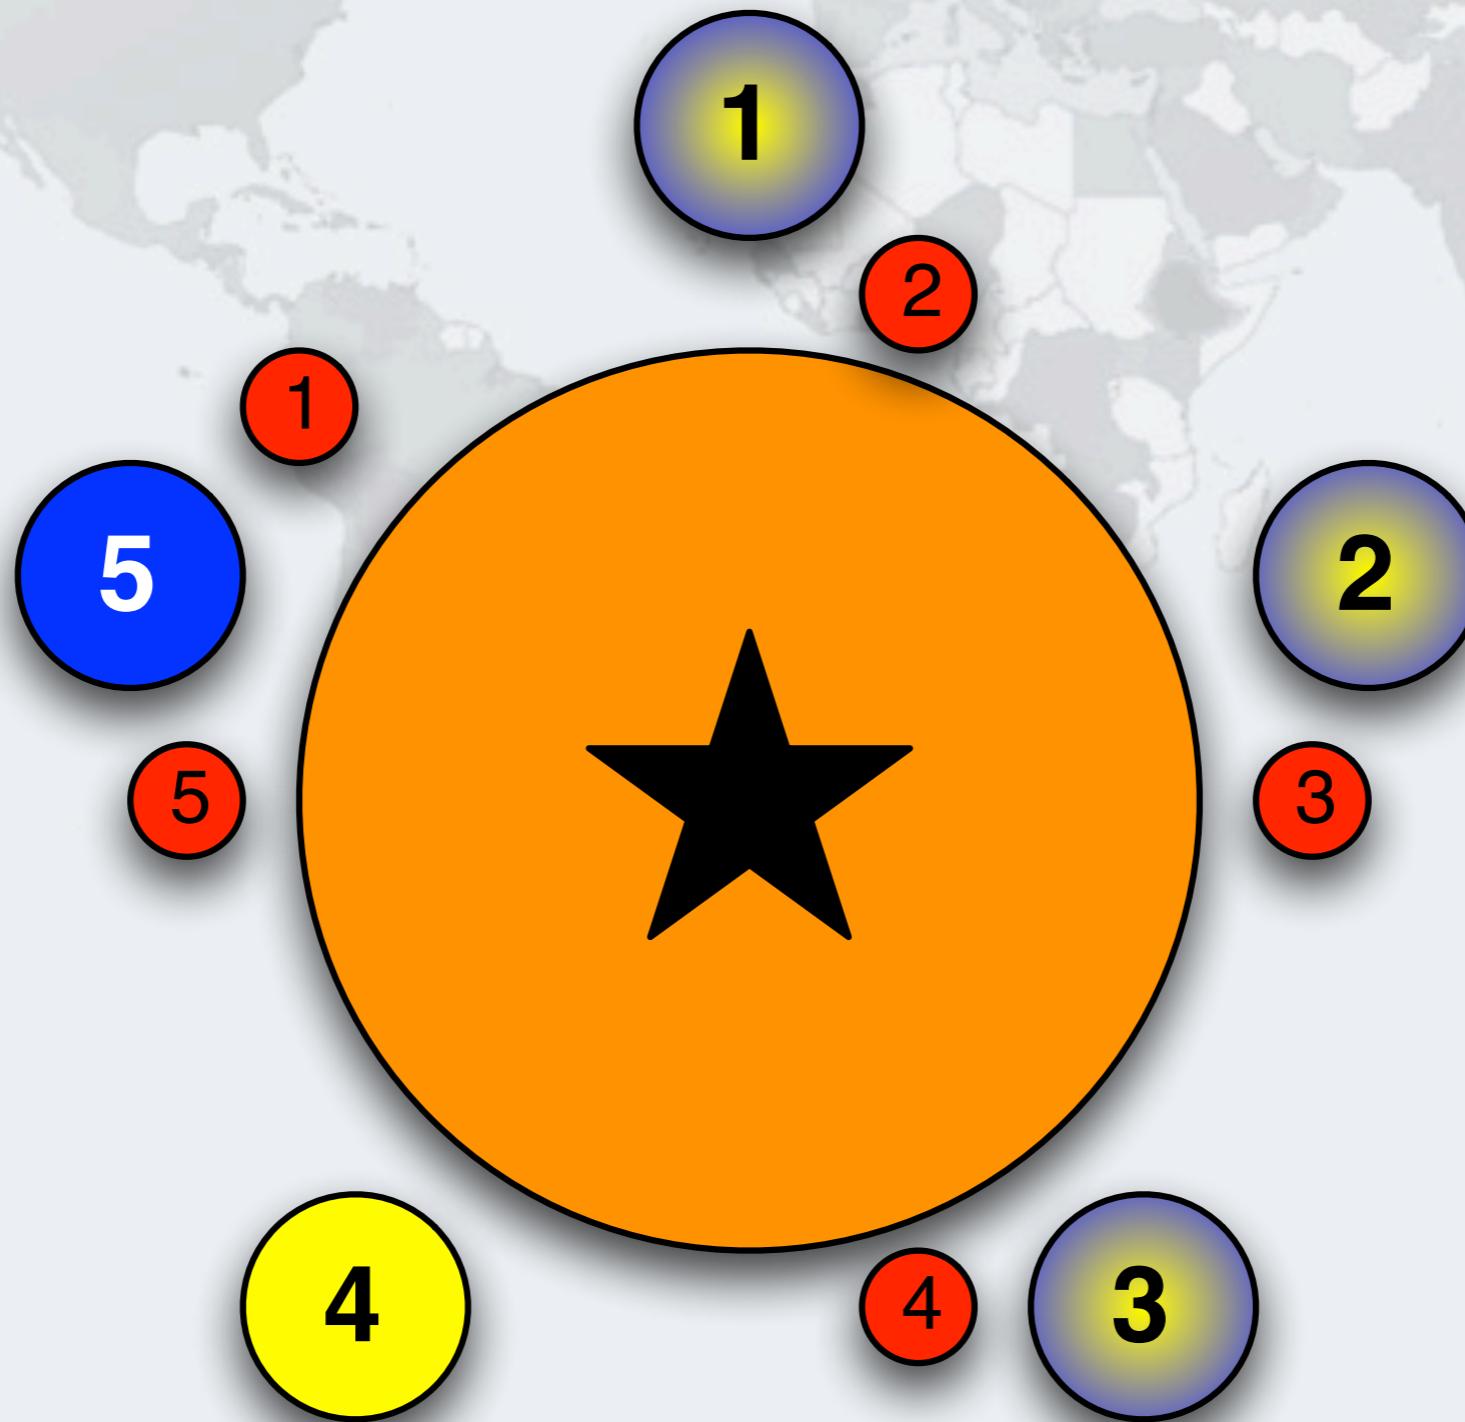

## Philosopher 1 Returns Cup 1

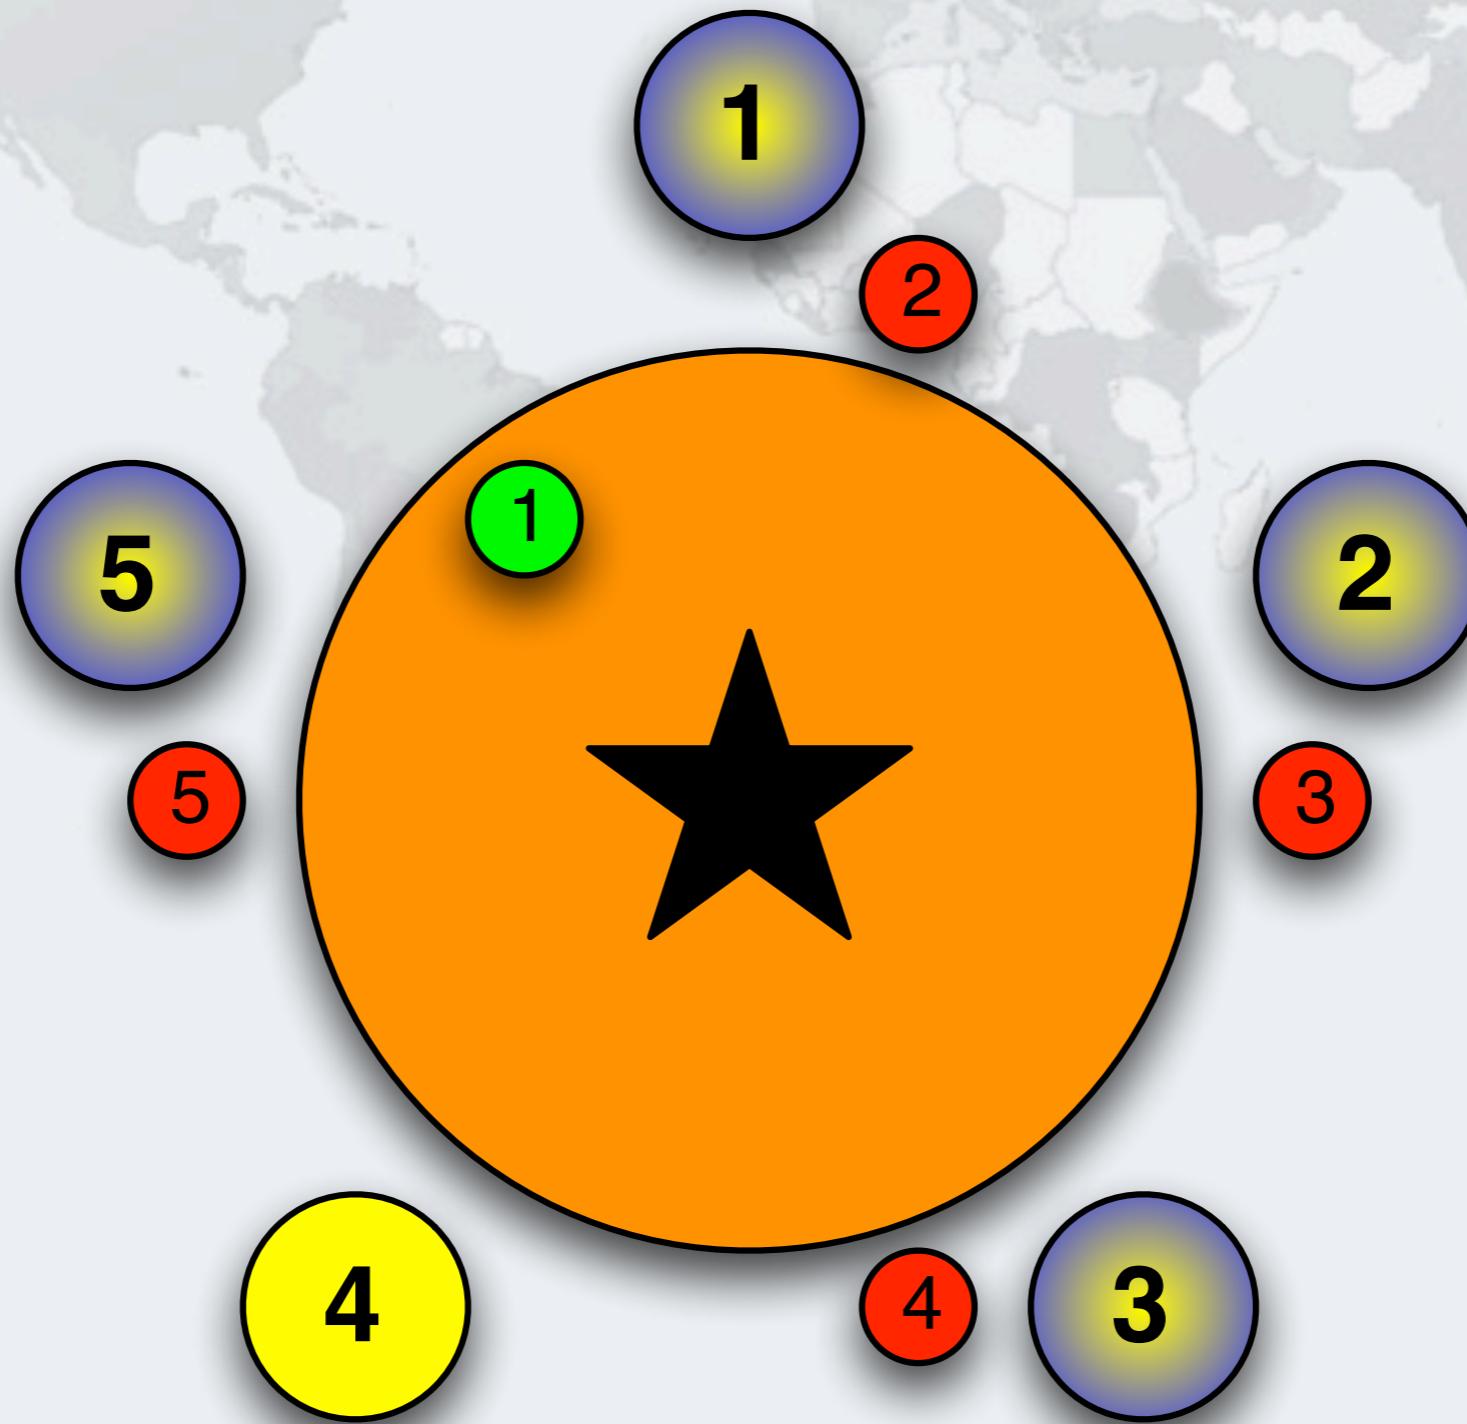

- Cups are returned in the opposite order to what they are acquired

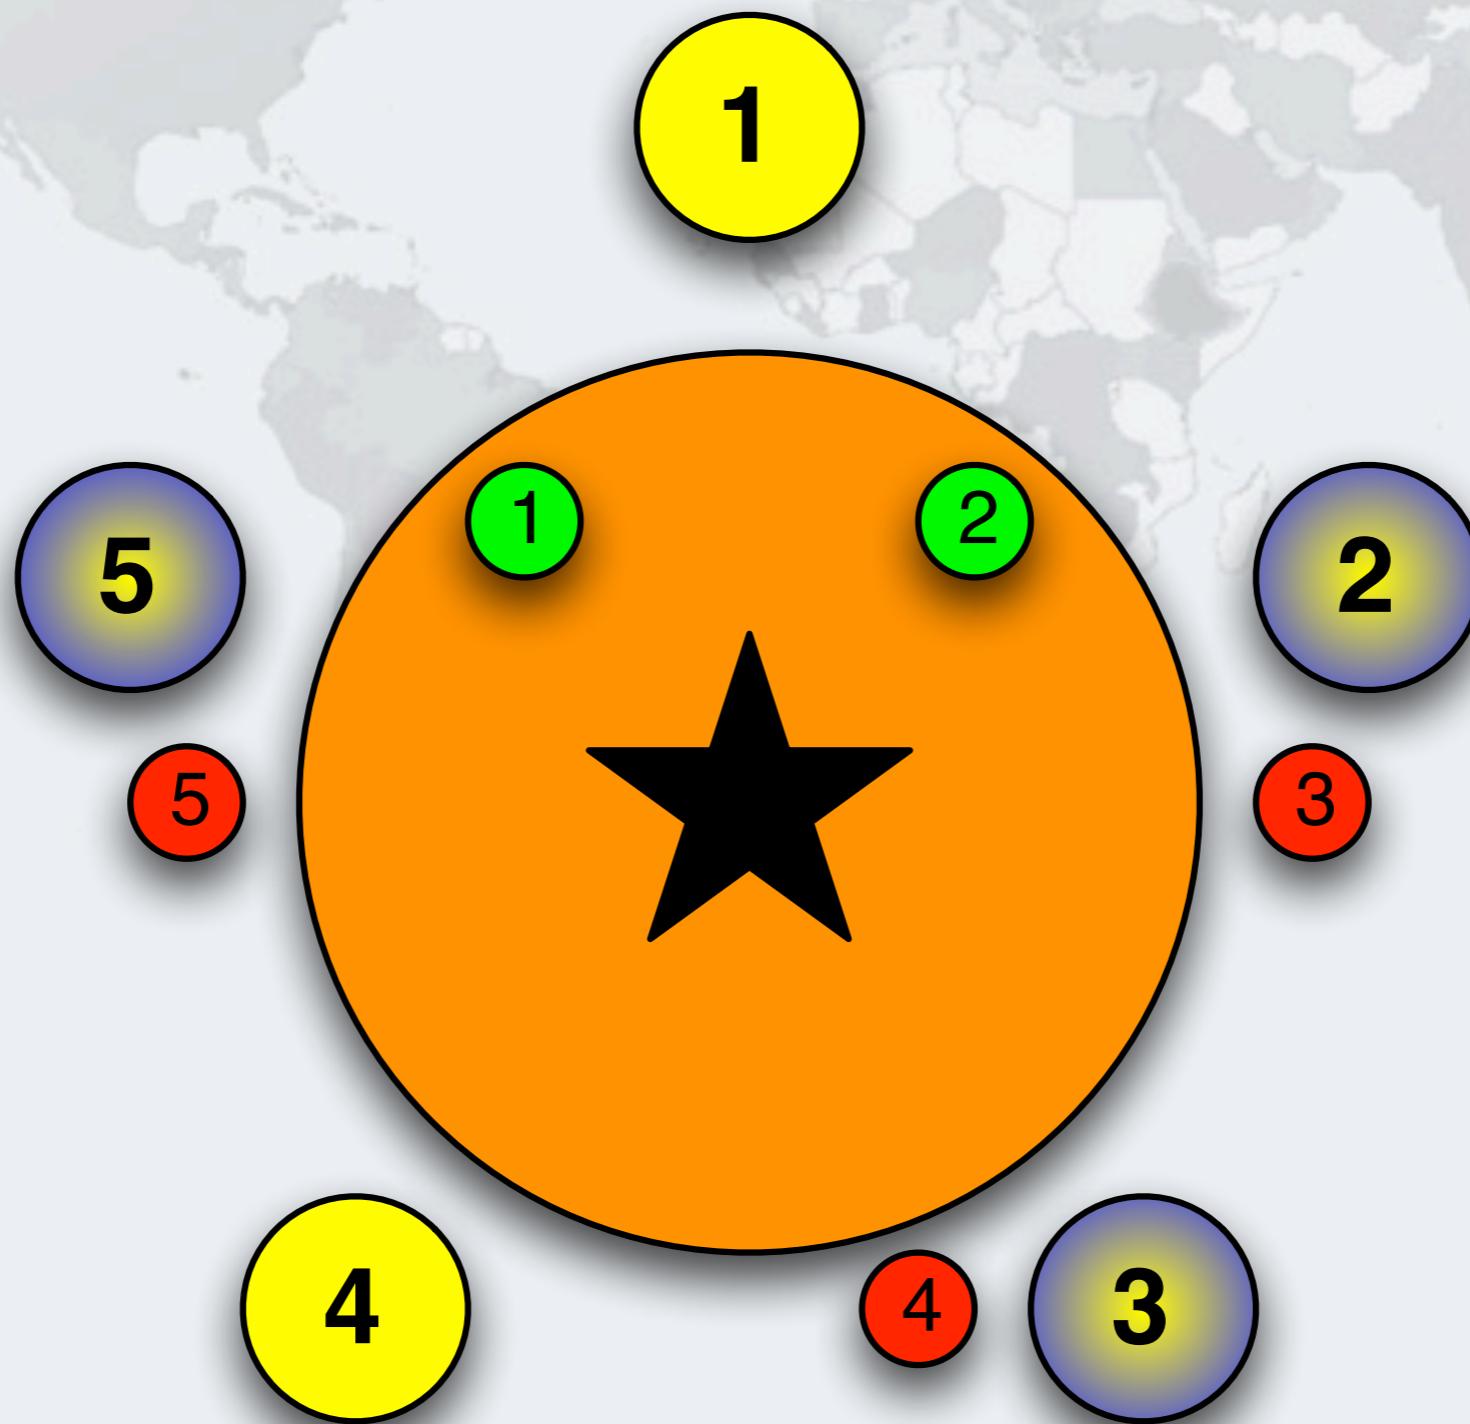

# Philosopher 5 Takes Cup 1 - Drinking

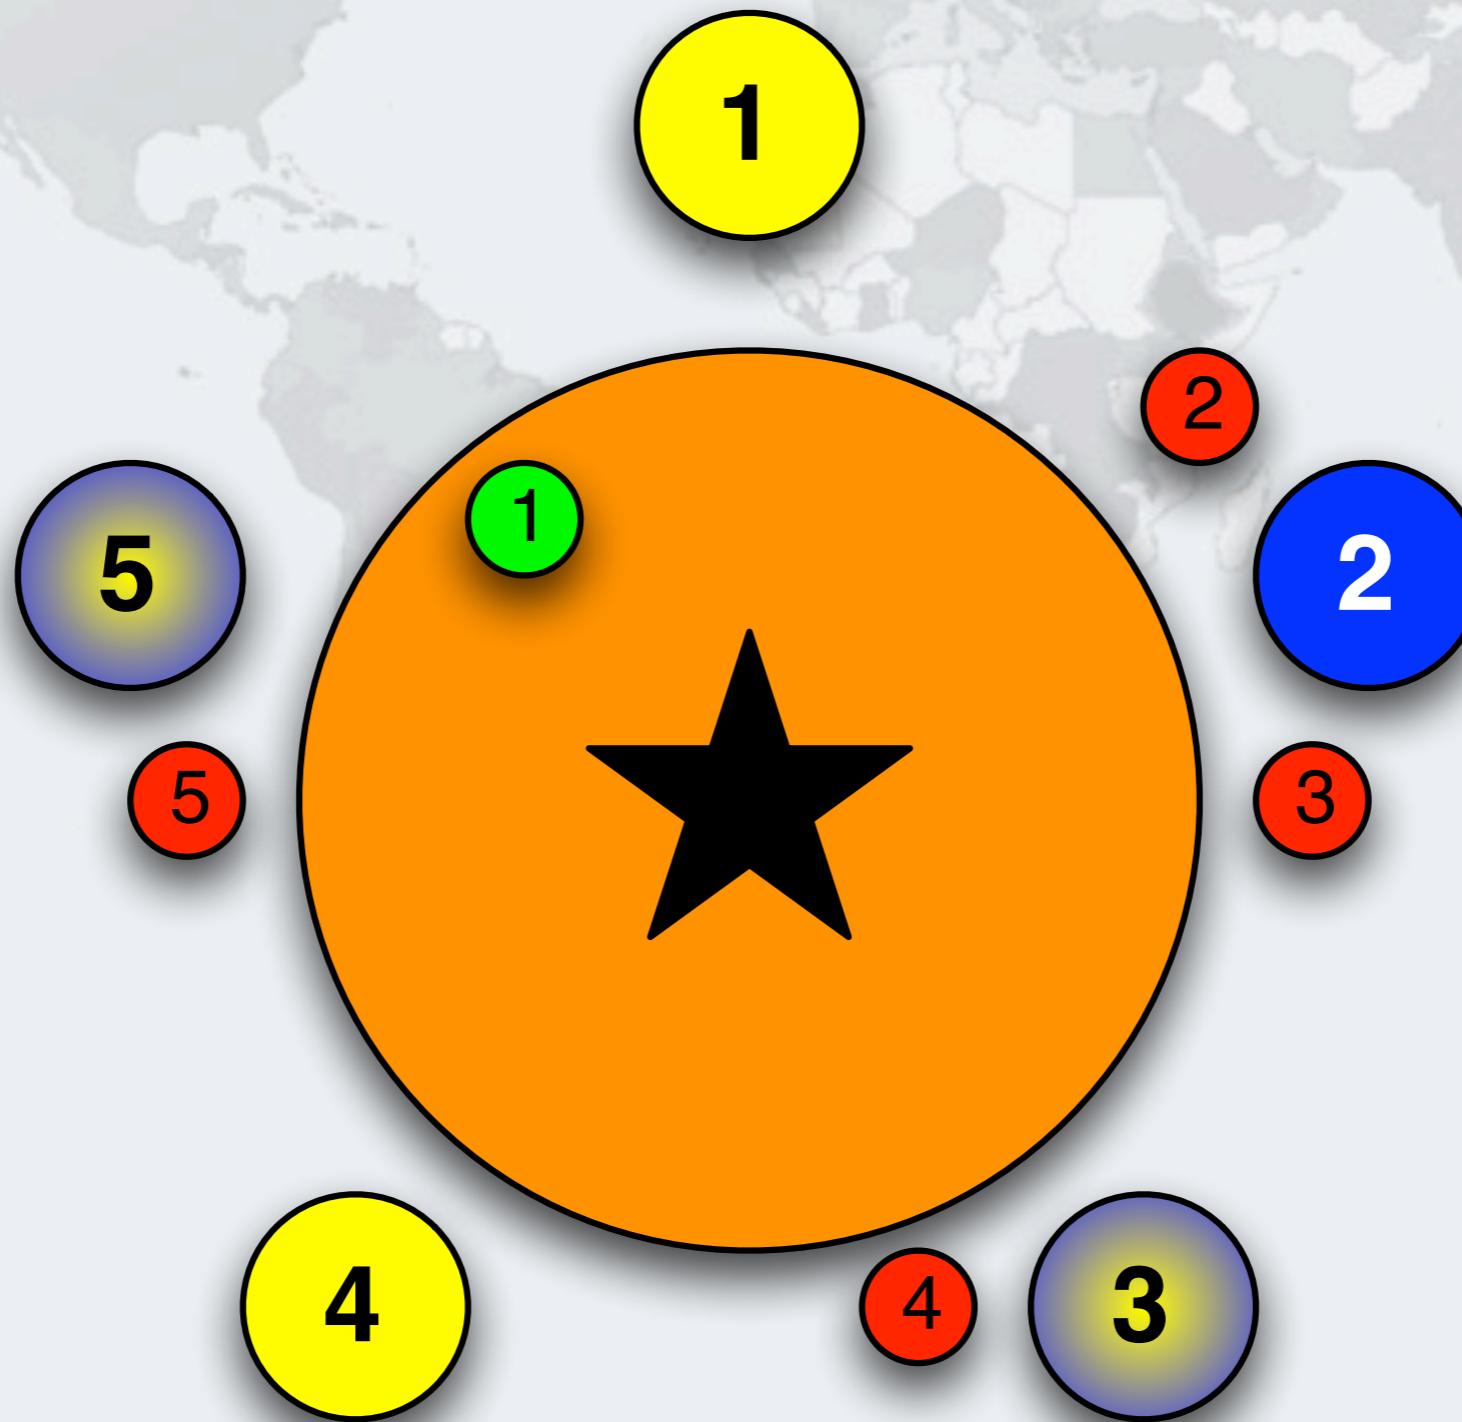

# Philosopher 5 Returns Cup 1

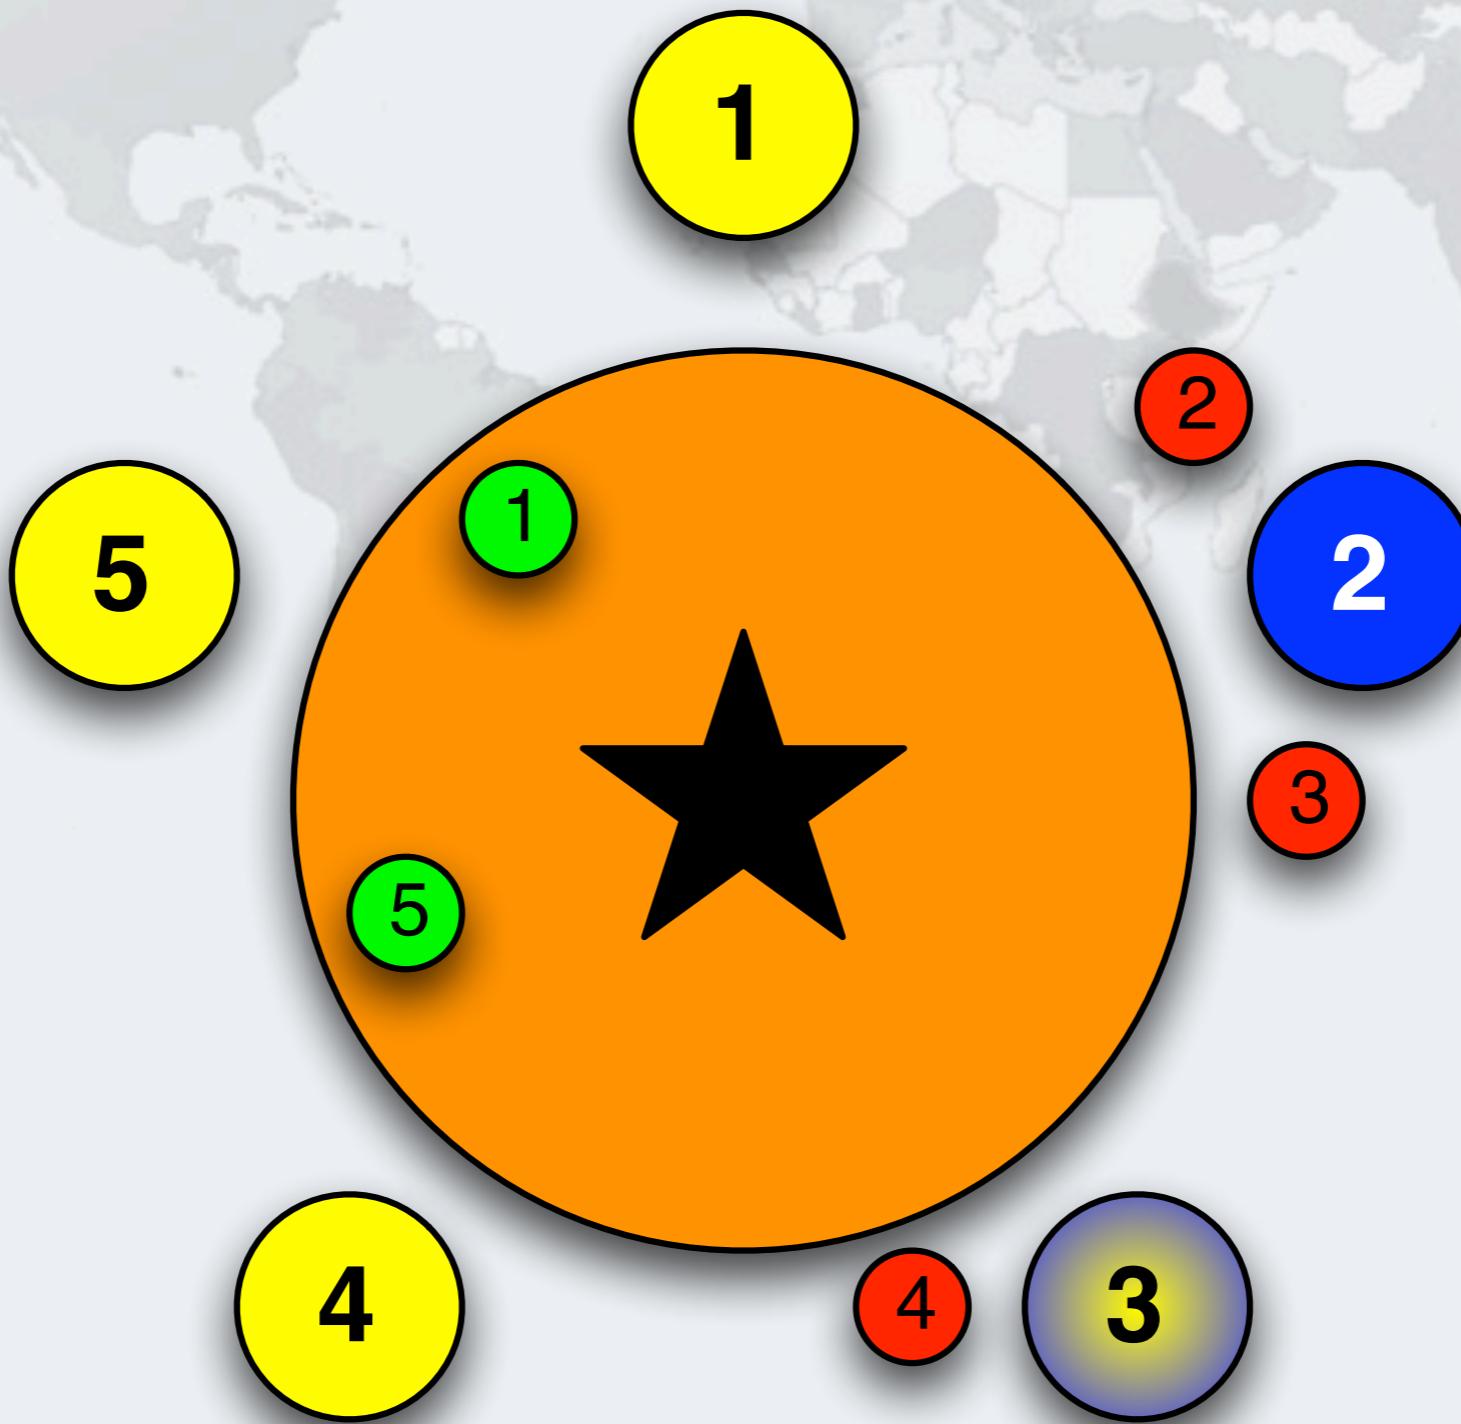

# Philosopher 1 Returns Cup 2

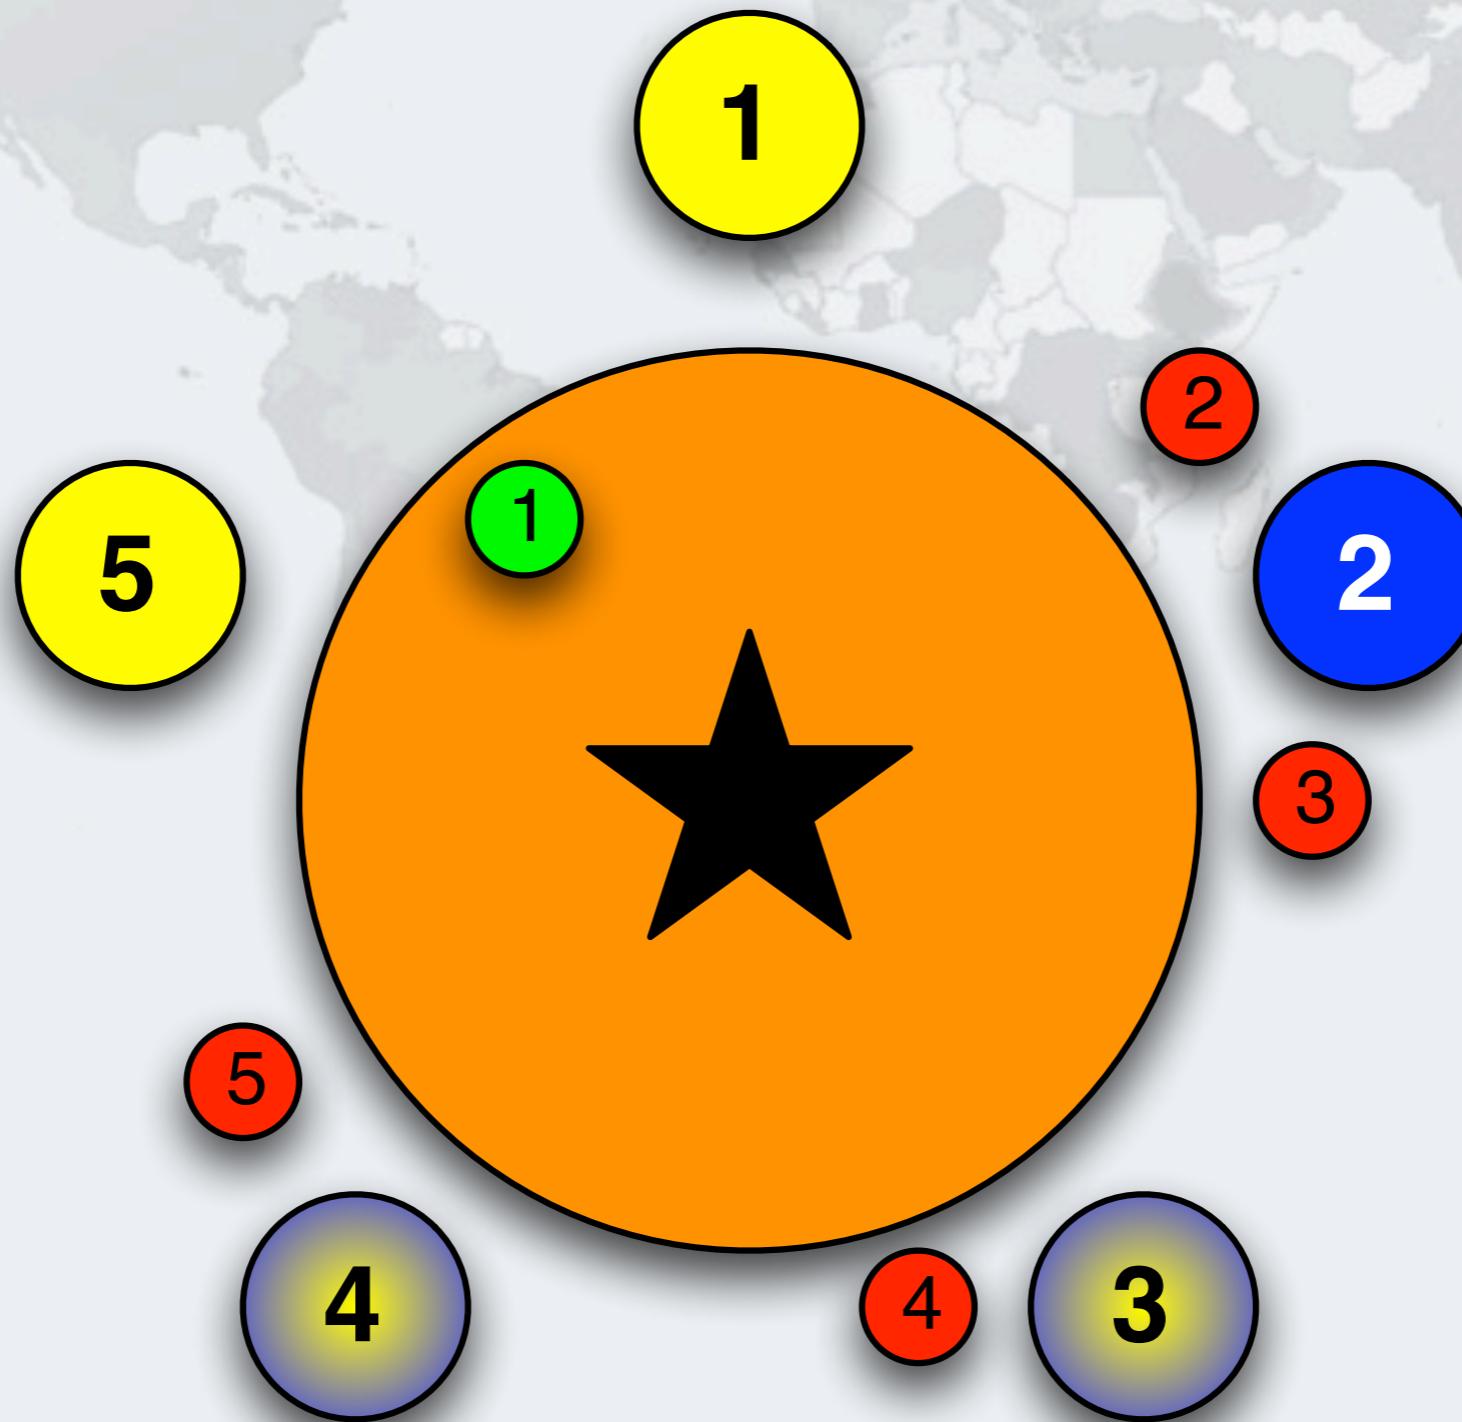

## Philosopher 2 Takes Cup 2 - Drinking

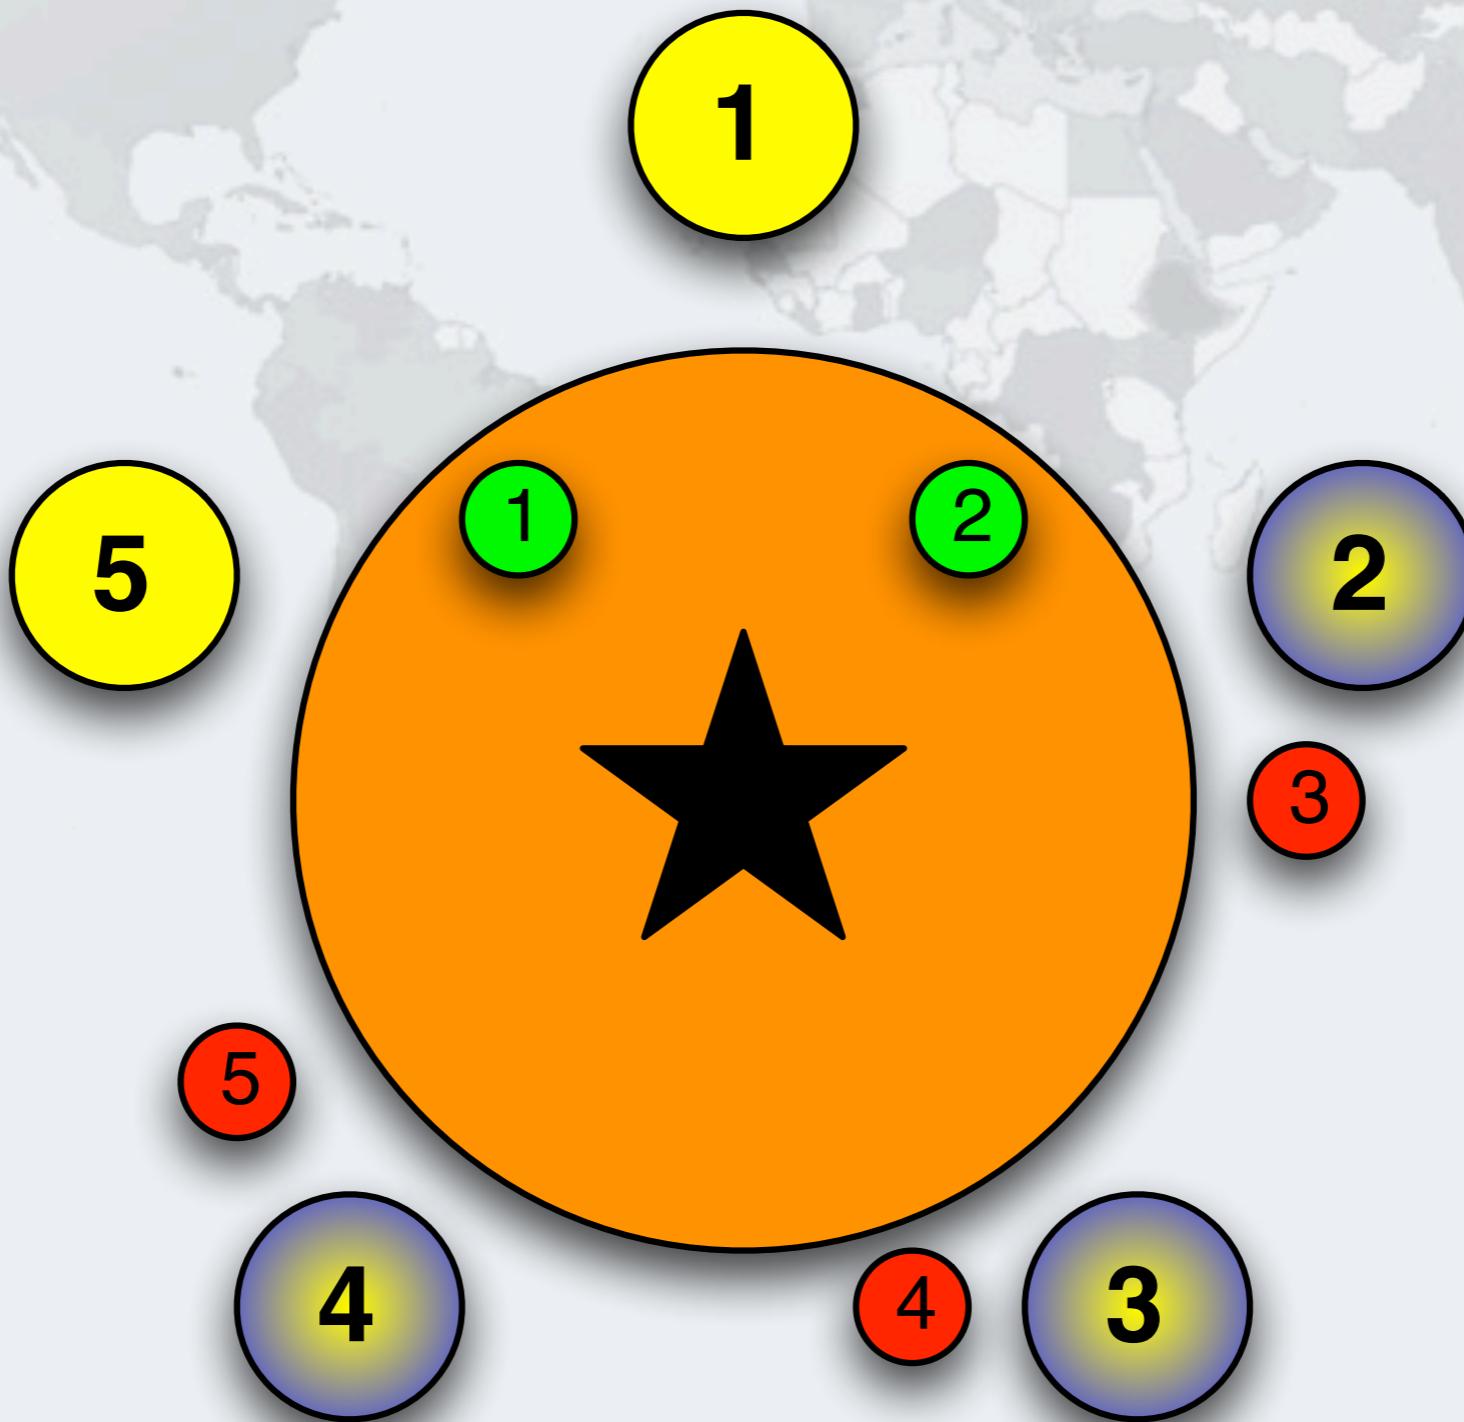

# Philosopher 5 Returns Cup 5

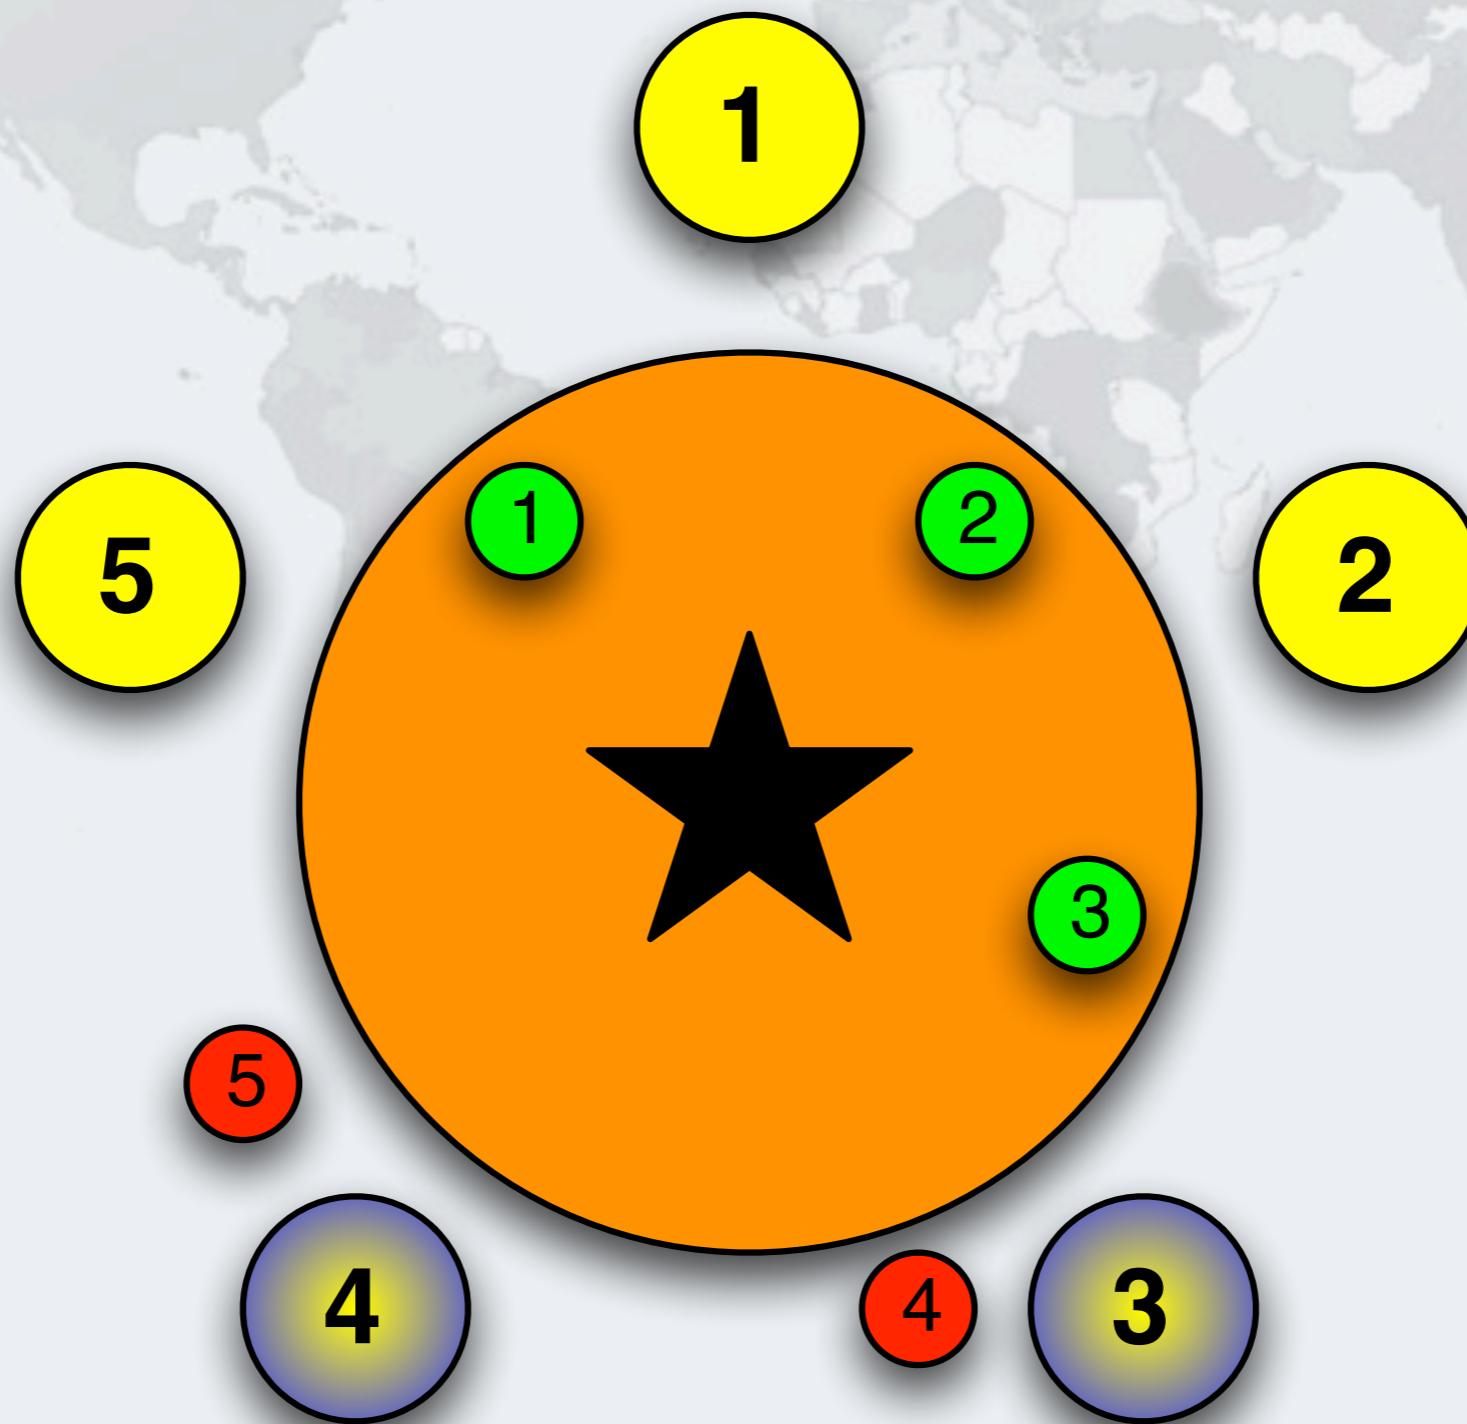

# Philosopher 4 Takes Cup 5

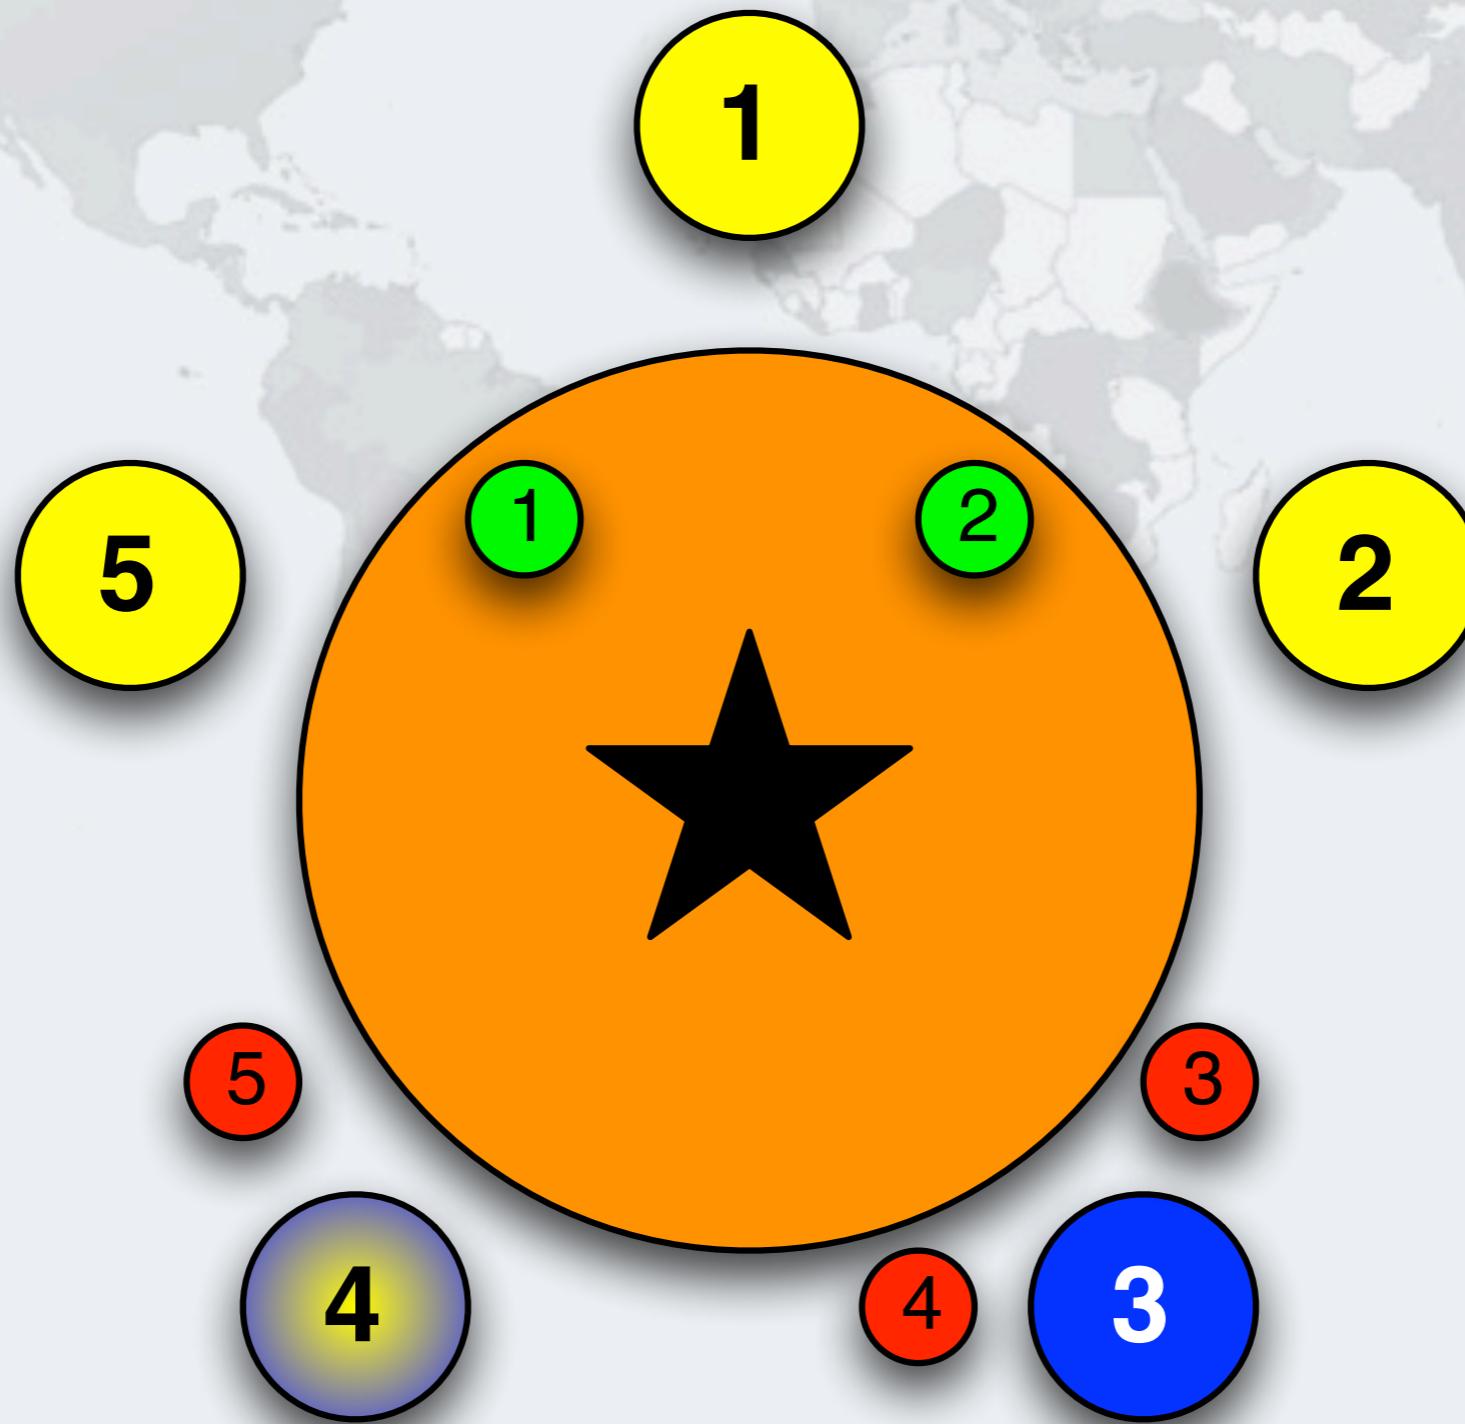

## Philosopher 2 Returns Cup 2

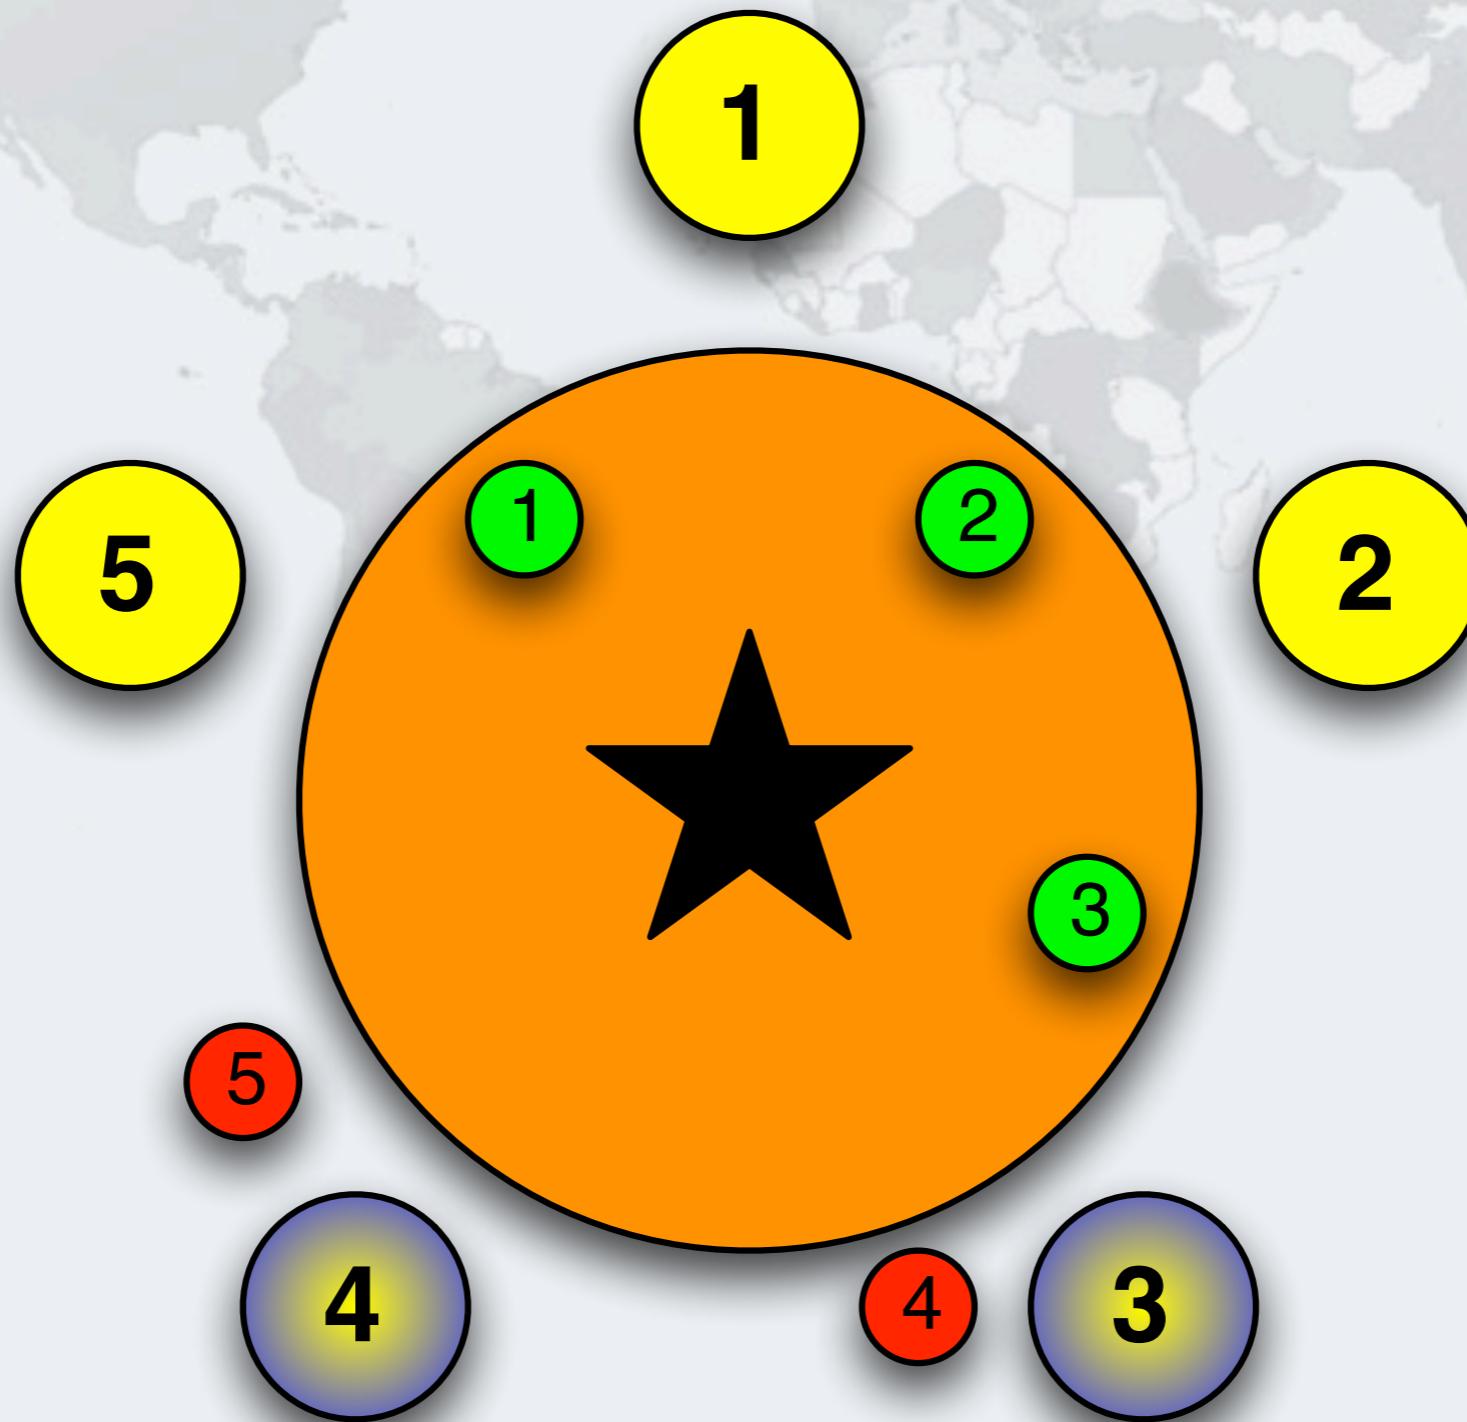

## Philosopher 2 Returns Cup 3

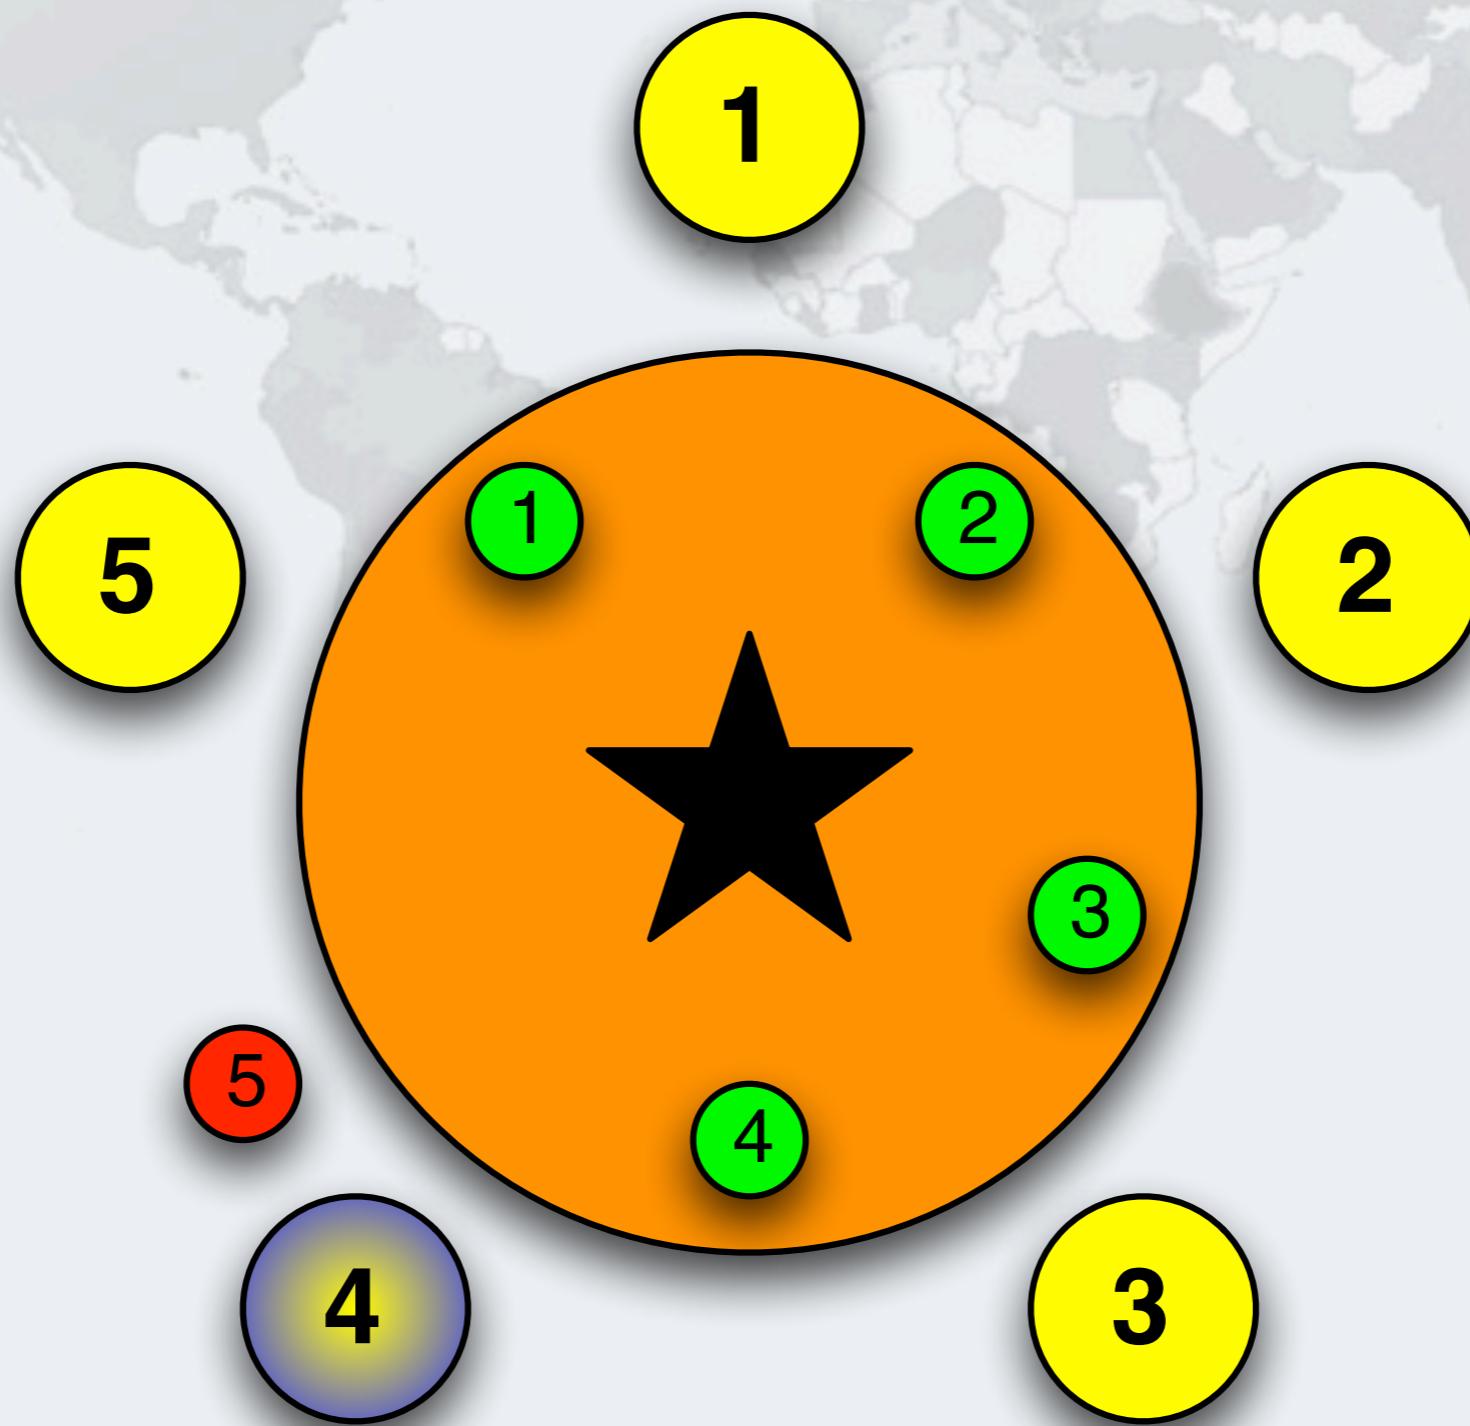

# Philosopher 3 Takes Cup 3 - Drinking

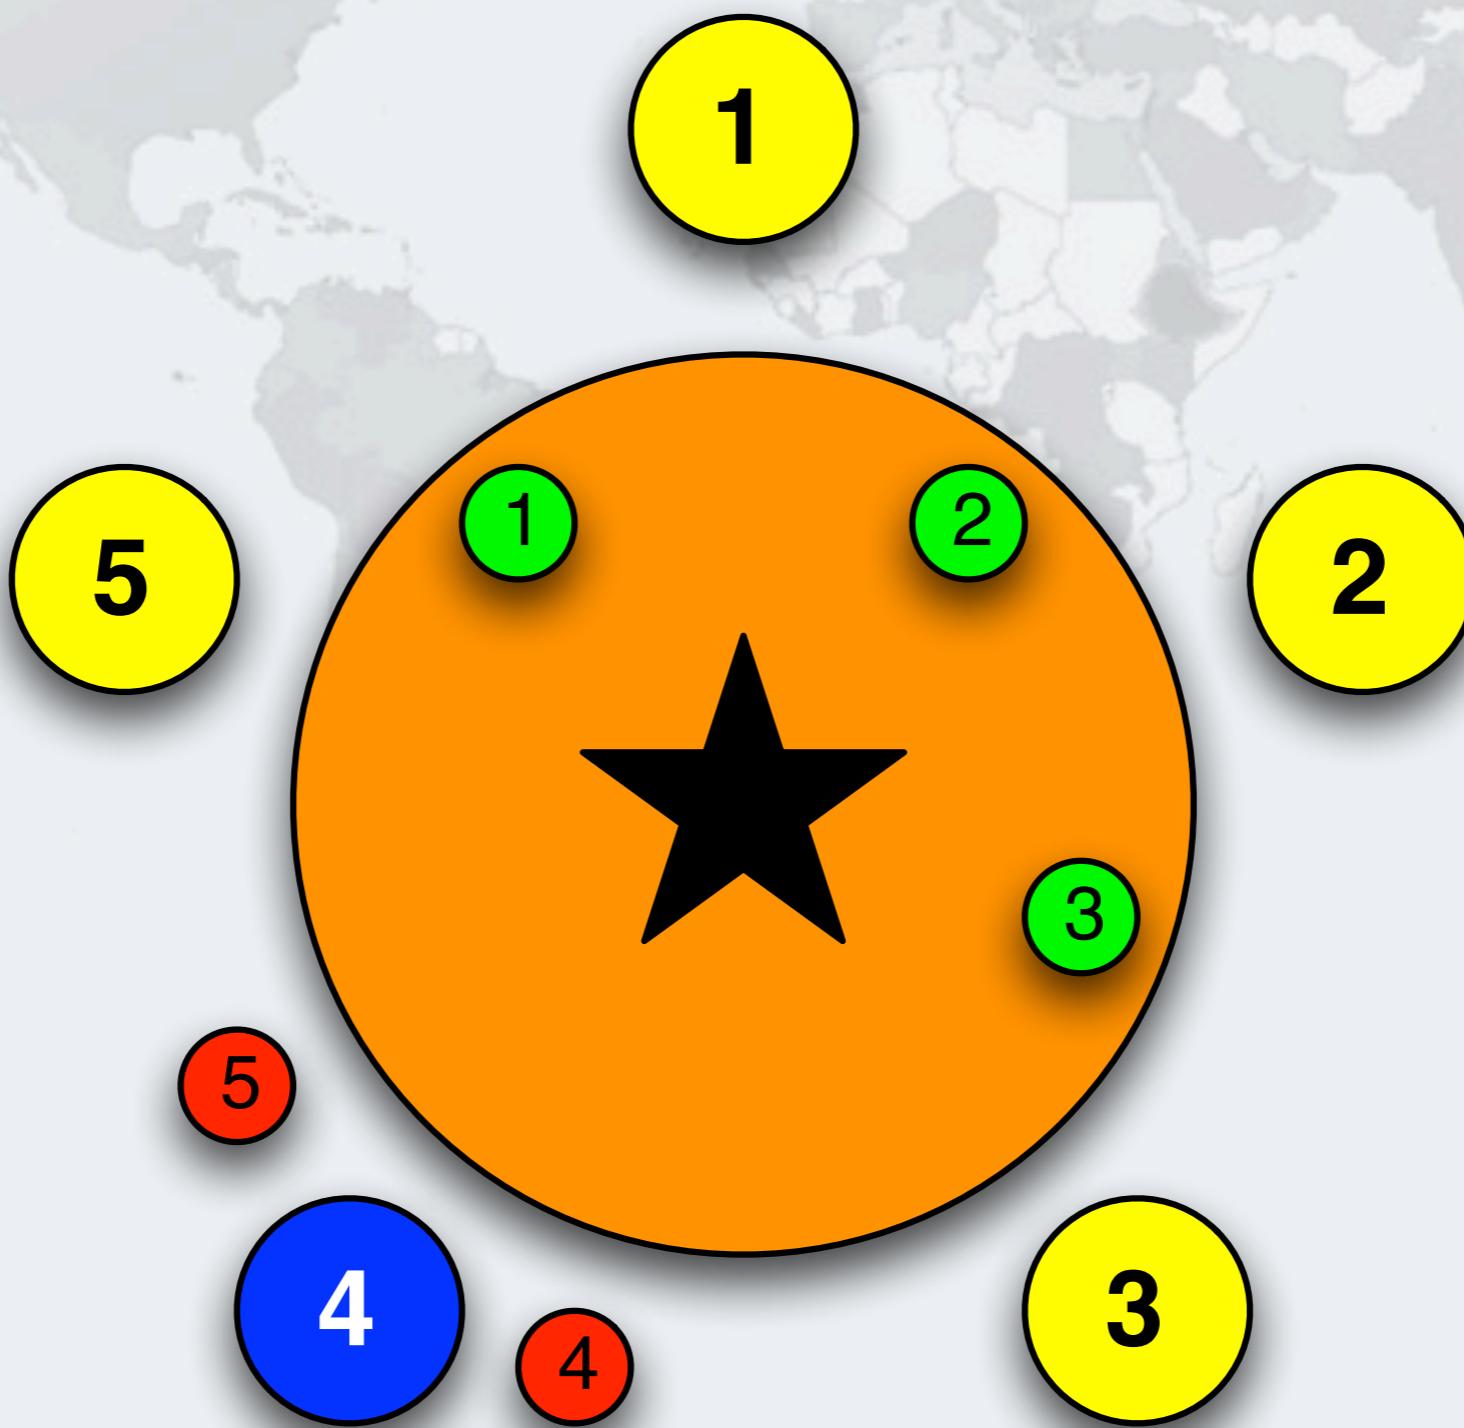

# Philosopher 3 Returns Cup 3

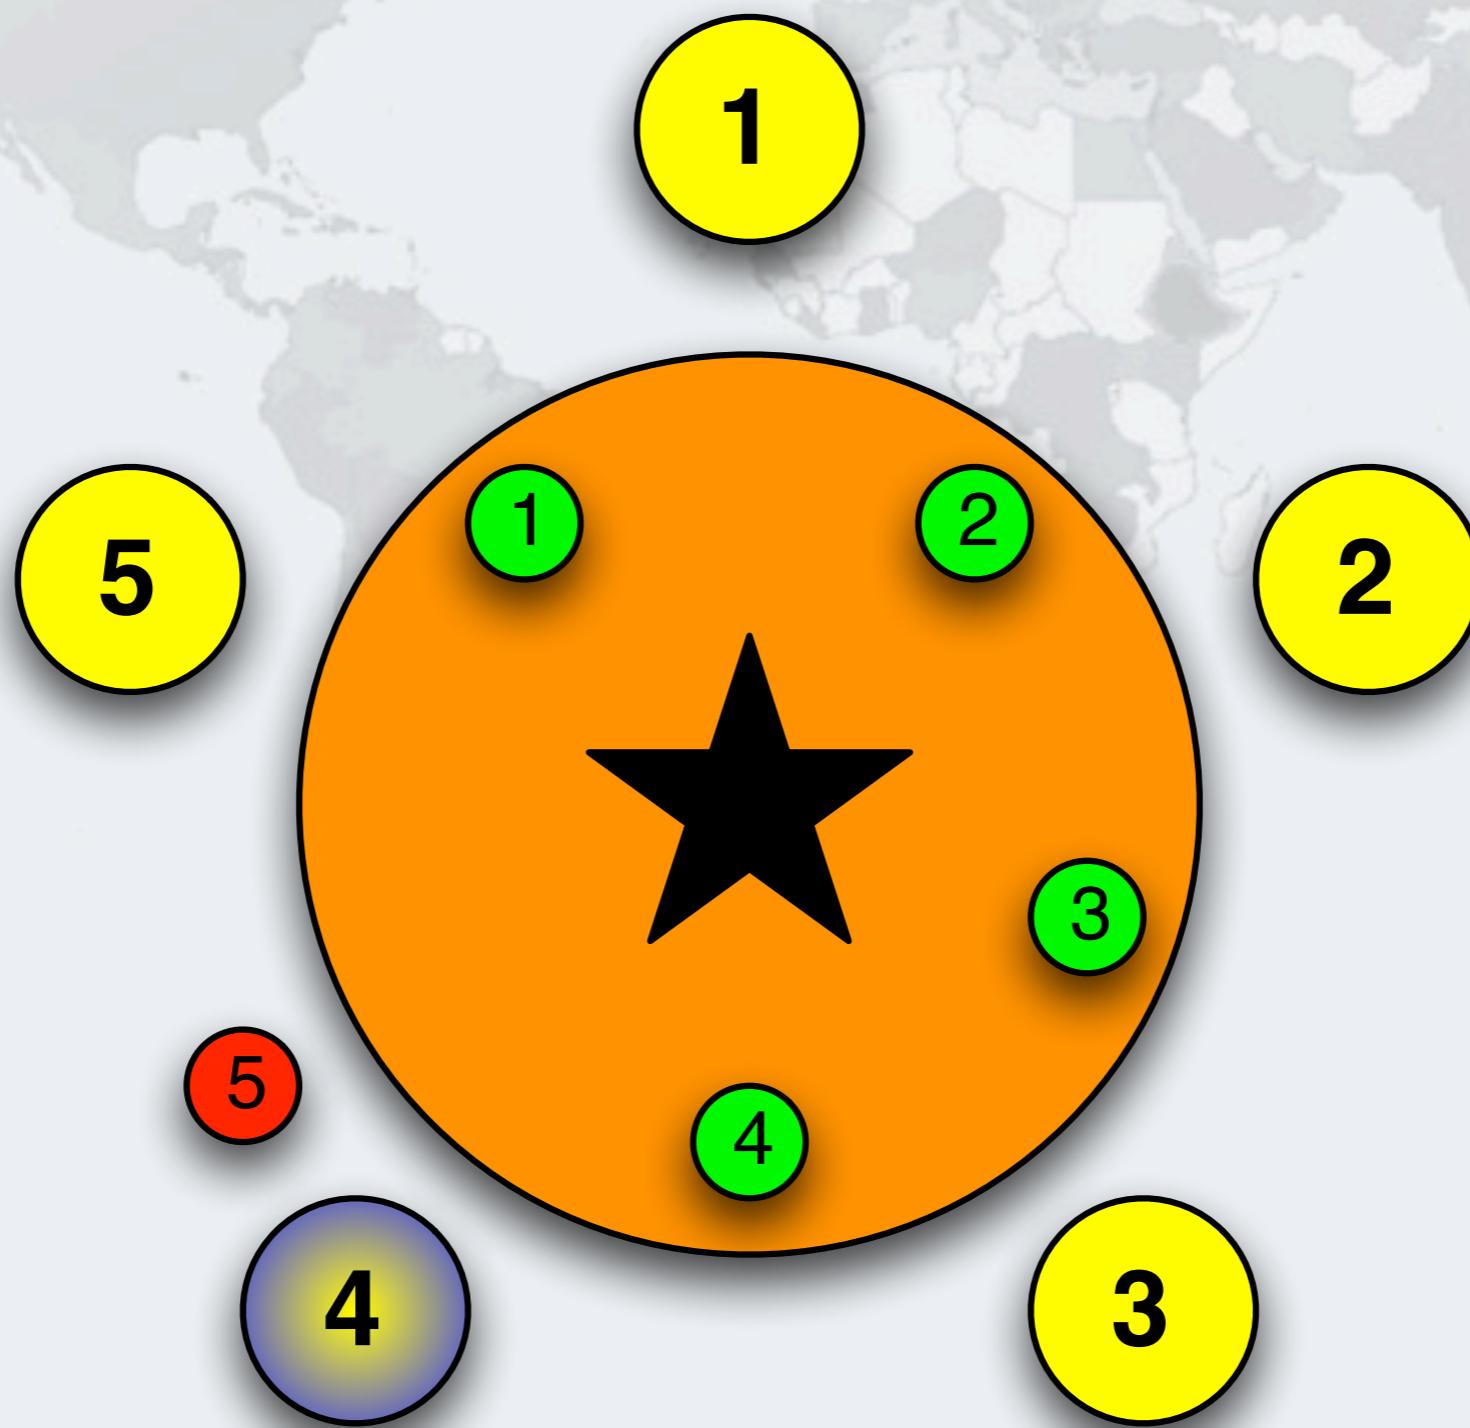

# Philosopher 3 Returns Cup 4

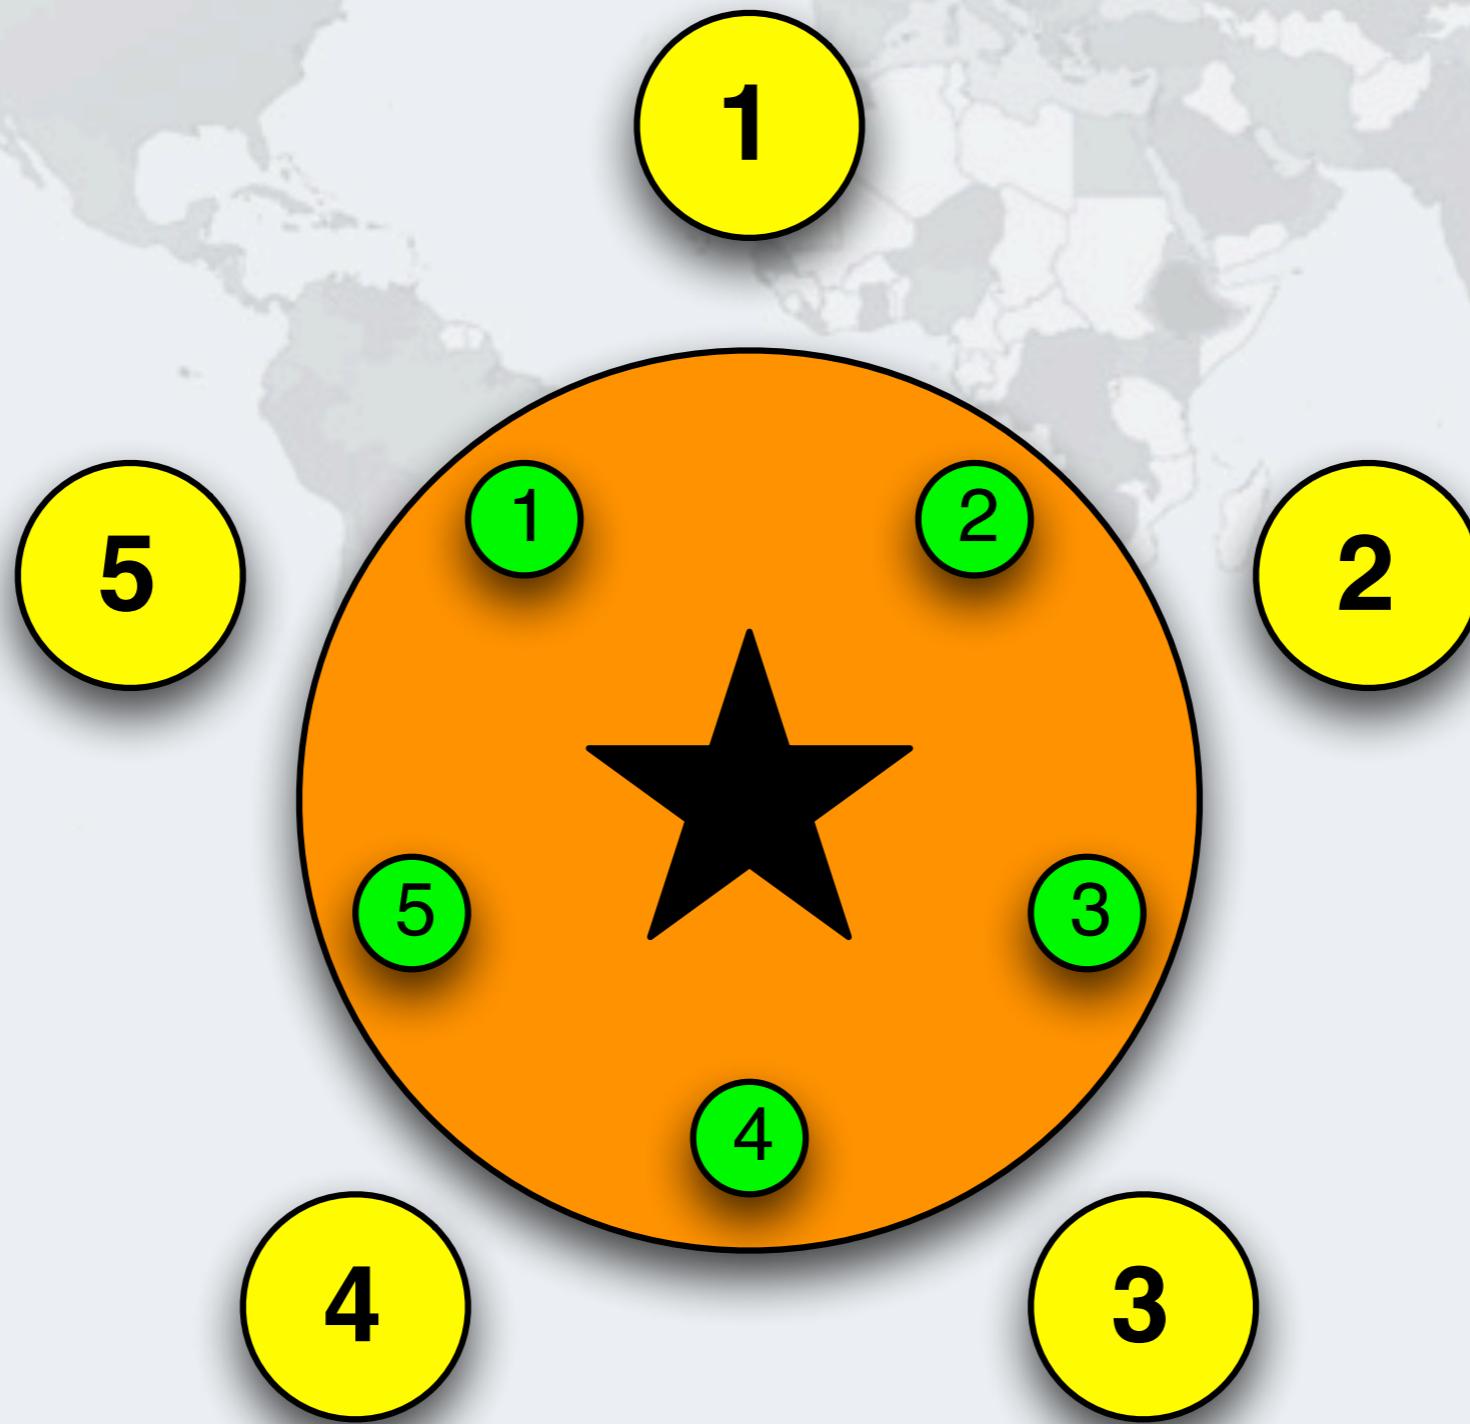

## Philosopher 4 Takes Cup 4 - Drinking

# Philosopher 4 Returns Cup 4

# Philosopher 4 Returns Cup 5

## Dynamic Lock Order Deadlocks

- The LeftRightDeadlock example had an obvious deadlock
- Often, it is not obvious what the lock instances are, e.g.

```
public boolean transferMoney(  
    Account from, Account to,  
    DollarAmount amount) {  
    synchronized (from) {  
        synchronized (to) {  
            return doActualTransfer(from, to, amount);  
        }  
    }  
}
```

## Checking Locks Are Held

- In our `doActualTransfer()`, assert we hold both locks

```
private boolean doActualTransfer(  
    Account from, Account to, DollarAmount amount) {  
    assert Thread.holdsLock(from);  
    assert Thread.holdsLock(to);  
    if (from.getBalance().compareTo(amount) >= 0) {  
        from.debit(amount);  
        to.credit(amount);  
        return true;  
    }  
    return false;  
}
```

# Causing The Deadlock With Transferring Money

- Giorgos has accounts in Switzerland and in Greece
  - He keeps on transferring money between them
    - Whenever new taxes are announced, he brings money into Greece
    - Whenever he gets any money paid, he transfers it to Switzerland
    - Sometimes these transfers can coincide
- Thread 1 is moving money from UBS to Alpha Bank

```
transferMoney(ubs, alpha, new DollarAmount(1000));
```
- Thread 2 is moving money from Alpha Bank to UBS

```
transferMoney(alpha, ubs, new DollarAmount(2000));
```
- If this happens at the same time, it can deadlock

# Fixing Dynamic Lock-Ordering Deadlocks

- The locks for `transferMoney()` are outside our control
  - They could be sent to us in any order
- We can *induce* an ordering on the locks
  - For example, we can use `System.identityHashCode()` to get a number representing this object
    - Since this is a 32-bit int, it is technically possible that two different objects have exactly the same identity hash code
    - In that case, we have a static lock to avoid a deadlock

```
public boolean transferMoney(Account from, Account to,
                           DollarAmount amount) {
    int fromHash = System.identityHashCode(from);
    int toHash = System.identityHashCode(to);
    if (fromHash < toHash) {
        synchronized (from) {
            synchronized (to) {
                return doActualTransfer(from, to, amount);
            }
        }
    } else if (fromHash > toHash) {
        synchronized (to) {
            synchronized (from) {
                return doActualTransfer(from, to, amount);
            }
        }
    } else {
        synchronized (tieLock) {
            synchronized (from) {
                synchronized (to) {
                    return doActualTransfer(from, to, amount);
                }
            }
        }
    }
}
```

# Imposing Natural Order

- Instead of `System.identityHashCode()`, we define an order
  - Such as account number, employee number, etc.
  - Or an order defined for the locks used

```
public class MonitorLock implements Comparable<MonitorLock> {  
    private static AtomicLong nextLockNumber = new AtomicLong();  
    private final long lockNumber = nextLockNumber.getAndIncrement();  
  
    public int compareTo(MonitorLock o) {  
        if (lockNumber < o.lockNumber) return -1;  
        if (lockNumber > o.lockNumber) return 1;  
        return 0;  
    }  
  
    public static MonitorLock[] makeGlobalLockOrder(  
        MonitorLock... locks) {  
        MonitorLock[] result = locks.clone();  
        Arrays.sort(result);  
        return result;  
    }  
}
```

# Deadlocks Between Cooperating Objects

- In this example, the deadlock is more subtle
  - Taxi is an individual taxi with a location and a destination
  - Dispatcher represents a fleet of taxis
- Spot the deadlock

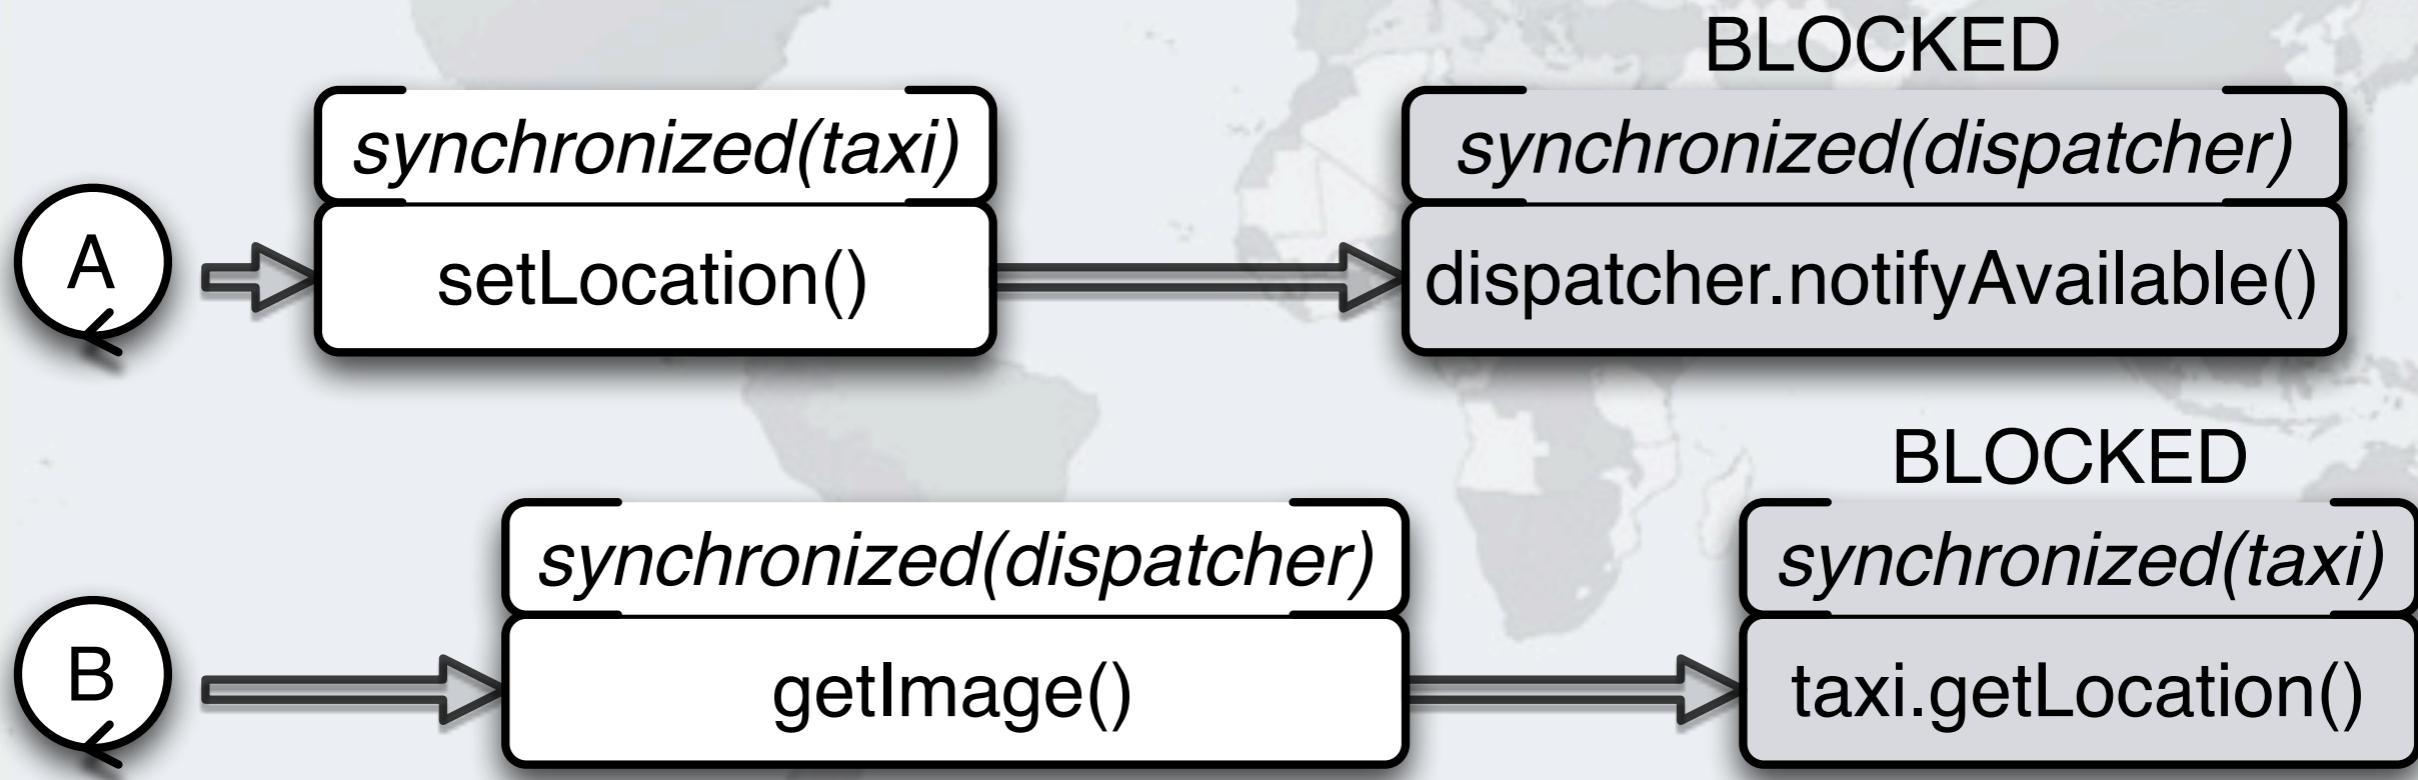

# Taxi, Representing An Individual Vehicle

```
public class Taxi {  
    @GuardedBy("this")  
    private Point location, destination;  
    private final Dispatcher dispatcher;  
  
    public Taxi(Dispatcher dispatcher) {  
        this.dispatcher = dispatcher;  
    }  
  
    public synchronized Point getLocation() {  
        return location;  
    }  
  
    public synchronized void setLocation(  
        Point location) {  
        this.location = location;  
        if (location.equals(destination))  
            dispatcher.notifyAvailable(this);  
    }  
}
```

# Dispatcher: Managing A Fleet Of Taxis

```
public class Dispatcher {  
    @GuardedBy("this")  
    private final Set<Taxi> taxis = new HashSet<>();  
    @GuardedBy("this")  
    private final Set<Taxi> availableTaxis = new HashSet<>();  
  
    public synchronized void notifyAvailable(Taxi taxi) {  
        availableTaxis.add(taxi);  
    }  
  
    public synchronized Image getImage() {  
        Image image = new Image();  
        for (Taxi taxi : taxis) {  
            image.drawMarker(taxi.getLocation());  
        }  
        return image;  
    }  
}
```

# How To Deadlock The Taxi Industry

- Or in Greece you can simply announce that you will deregulate the taxi industry - that causes *real* deadlocks
  - In 2011, at height of tourist season, taxis went on strike for 3 weeks!

## Open Calls

- Calling an *alien method* with a lock held is difficult to analyze and therefore risky
- Both Taxi and Dispatcher break this rule
- Calling a method with no locks held is called an *open call*
  - Makes it much easier to reason about liveness

## Refactored Taxi.setLocation()

- We should not call *alien methods* whilst holding locks
- Here we split the method up into parts that need the lock and those that call alien methods

```
public void setLocation(Point location) {  
    boolean reachedDestination;  
    synchronized (this) {  
        this.location = location;  
        reachedDestination = location.equals(destination);  
    }  
    if (reachedDestination) {  
        dispatcher.notifyAvailable(this);  
    }  
}
```

## Refactored Dispatcher.getImage()

- We make a copy of the set to prevent race conditions

```
public Image getImage() {  
    Set<Taxi> copy;  
    synchronized (this) {  
        copy = new HashSet<>(taxis);  
    }  
    Image image = new Image();  
    for (Taxi taxi : copy) {  
        image.drawMarker(taxi.getLocation());  
    }  
    return image;  
}
```

## Benefit Of Open Calls

- Strive to use open calls throughout your program
- Programs that rely on open calls are far easier to analyze for deadlock-freedom than those that allow calls to alien methods with locks held
- Alien method calls with lock held are probably the biggest cause of deadlocks "in the field"

# Open Call In Vector

- In Sun Java 6 `Vector.writeObject()` method is synchronized
  - This is to provide thread safety during writing

```
private synchronized void writeObject(ObjectOutputStream s)
    throws IOException {
    s.defaultWriteObject();
}
```

- However, since it calls the alien "defaultWriteObject()" it can deadlock
  - <http://www.javaspecialists.eu/archive/Issue184.html>

# IBM Avoids This Problem With An Open Call

```
private void writeObject(ObjectOutputStream stream)
    throws IOException {
Vector<E> cloned = null;
// this specially fix is for a special dead-lock in customer
// program: two vectors refer each other may meet dead-lock in
// synchronized serialization. Refer CMVC-103316.1
```

```
synchronized (this) {
    try {
        cloned = (Vector<E>) super.clone();
        cloned.elementData = elementData.clone();
    } catch (CloneNotSupportedException e) {
        // no deep clone, ignore the exception
    }
}
cloned.writeObjectImpl(stream);
}
```

```
private void writeObjectImpl(ObjectOutputStream stream)
    throws IOException {
stream.defaultWriteObject();
}
```

## OpenJDK 7 Also Uses An Open Call

```
private void writeObject(ObjectOutputStream s)
    throws IOException {
final ObjectOutputStream.PutField fields = s.putFields();
final Object[] data;
synchronized (this) {
    fields.put("capacityIncrement", capacityIncrement);
    fields.put("elementCount", elementCount);
    data = elementData.clone();
}
fields.put("elementData", data);
s.writeFields();
}
```

## Resource Deadlocks

- We can also cause deadlocks waiting for resources
- For example, say you have two DB connection pools
  - Some tasks might require connections to both databases
  - Thus thread A might hold semaphore for D1 and wait for D2, whereas thread B might hold semaphore for D2 and be waiting for D1
- Thread dump and ThreadMXBean does not show this as a deadlock!

## Our DatabasePool - Connect() And Disconnect()

```
public class DatabasePool {  
    private final Semaphore connections;  
    public DatabasePool(int connections) {  
        this.connections = new Semaphore(connections);  
    }  
  
    public void connect() {  
        connections.acquireUninterruptibly();  
        System.out.println("DatabasePool.connect");  
    }  
  
    public void disconnect() {  
        System.out.println("DatabasePool.disconnect");  
        connections.release();  
    }  
}
```

# ThreadMXBean Does Not Detect This Deadlock

DatabasePool.connect  
DatabasePool.connect

The screenshot shows the VisualVM interface with the 'Threads' tab selected. On the left, a tree view lists various Java system threads like 'Reference Handler', 'Finalizer', etc., with 'Thread-0' being the currently selected thread. The main pane displays detailed information about Thread-0: its name is 'Thread-0', it is in a 'WAITING' state on a specific semaphore, and it has waited 2 times. Below this, the 'Stack trace:' section shows a deep call stack from 'sun.misc.Unsafe.park(Native Method)' up to the application code 'eu.javaspecialists.course.concurrency.ch10\_avoiding\_liveness\_hazards.DatabasePool.connect(DatabasePool.java:12)'. At the bottom of the interface, there is a 'Detect Deadlock' button which is highlighted with a blue border, and the message 'No deadlock detected'.

Detect Deadlock No deadlock detected

Detect Deadlock No deadlock detected

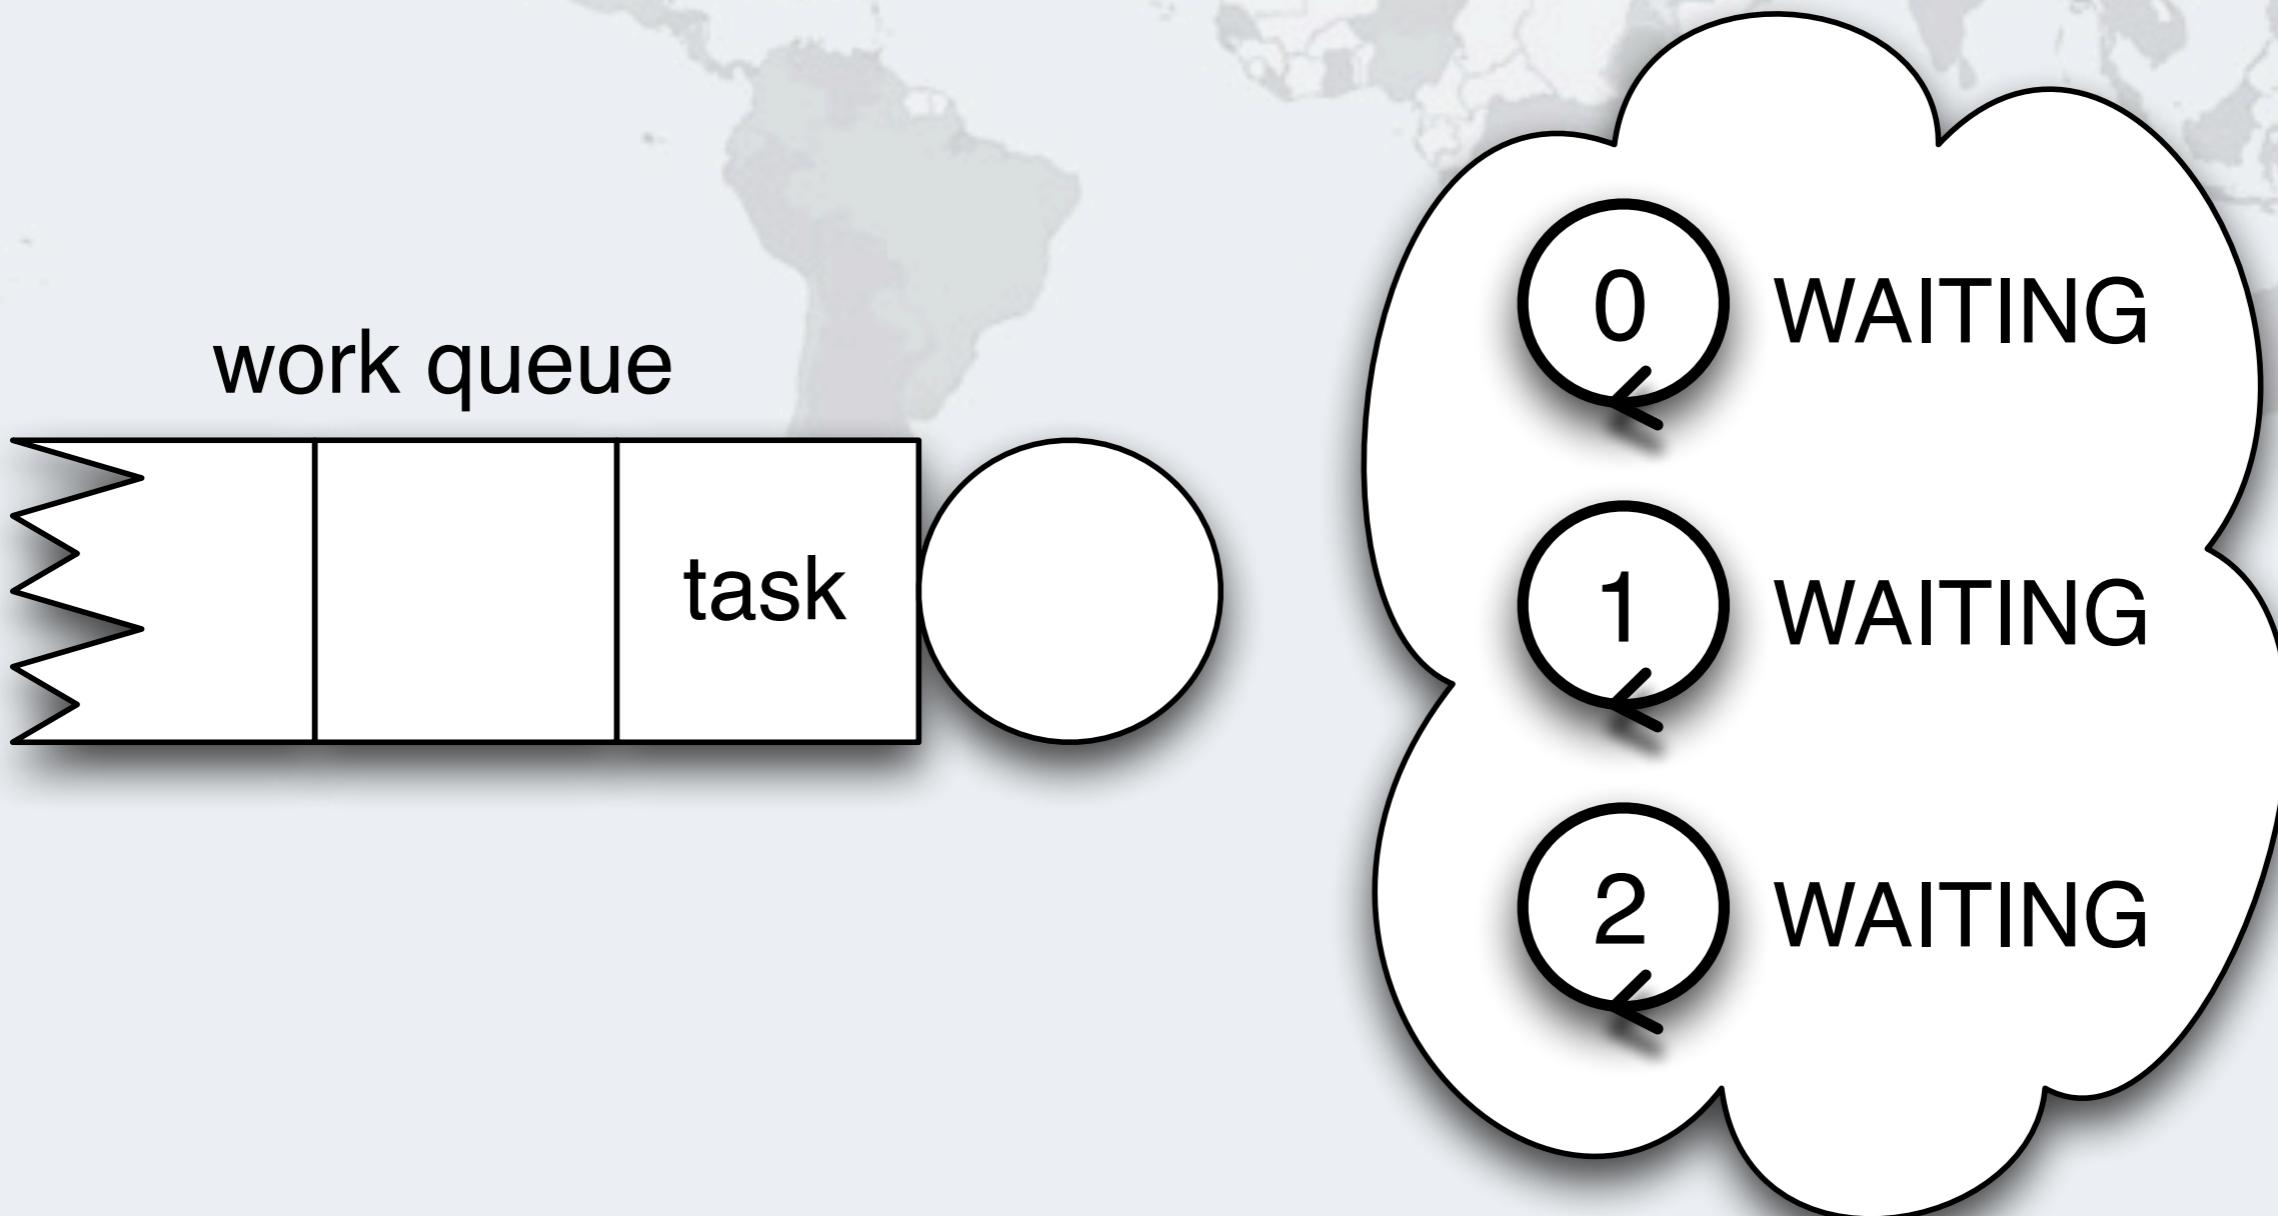

# Dependent Tasks Causing Liveness Issues

- Tasks that depend on others in pool can cause a thread-starvation deadlock

```
ExecutorService pool = Executors.newFixedThreadPool(3);
final CountDownLatch latch = new CountDownLatch(4);
for (int i = 0; i < 4; i++) {
    pool.submit(new Runnable() {
        public void run() {
            System.out.println("countdown");
            latch.countDown();
            try {
                System.out.println("waiting");
                latch.await();
            } catch (InterruptedException e) {
                System.out.println("interrupting");
                Thread.currentThread().interrupt();
            }
            System.out.println("done");
        }
    });
}
```

## Thread Pool Blocked Up

- All the threads are waiting for "task" to be completed
  - Bounded thread pools and bounded queues can cause deadlocks

## 10.2 Avoiding And Diagnosing Deadlocks

Avoiding Liveness Hazards

JavaSpecialists.eu  
java training

## 10.2 Avoiding And Diagnosing Deadlocks

- If you only ever acquire one lock, you cannot get a lock-ordering deadlock
  - This is the easiest way to avoid deadlocks, but not always practical
- If you need to acquire multiple locks, include lock ordering in your design
  - Important to specify and document possible lock sequences
  - Identify where multiple locks could be acquired
  - Do a global analysis to ensure that lock ordering is consistent
    - This can be extremely difficult in large programs
- Use open calls whenever possible
  - Do not call alien methods whilst holding a lock

# Unit Testing For Lock Ordering Deadlocks

- Code typically has to be called many times before a deadlock happens
- How many times do you need to call it to prove that there is no deadlock?
  - Nondeterministic unit tests are bad - they should either always pass or always fail

## Adding A Sleep To Cause Deadlocks

- In the `transferMoney()` method, a deadlock occurs if after the first lock is granted, the first thread is swapped out and another thread requests the second lock
- We can force this to happen by sleeping a short while after requesting the first lock

```
public class Bank {  
    public boolean transferMoney(Account from, Account to,  
                                DollarAmount amount) {  
        synchronized (from) {  
            sleepWhileForTesting();  
        synchronized (to) {  
            return doActualTransfer(from, to, amount);  
        }  
    }  
}  
protected void sleepWhileForTesting() {}
```

# In Our Unit Test We Override The Class

- We make the `sleepAWhileForTesting()` method sleep
  - In production, when we use only the normal Bank, the empty method will be optimized away by the HotSpot compiler

```
public class SlowBank extends Bank {  
    private final long timeout;  
    private final TimeUnit unit;  
    public SlowBank(long timeout, TimeUnit unit) {  
        this.timeout = timeout;  
        this.unit = unit;  
    }  
    protected void sleepAWhileForTesting() {  
        try {  
            unit.sleep(timeout);  
        } catch (InterruptedException e) {  
            Thread.currentThread().interrupt();  
        }  
    }  
}
```

# Verifying Thread Deadlocks

- **ThreadMXBean has two methods for finding deadlocks**
  - **findMonitorDeadlockedThreads()**
    - Includes only "monitor" locks, i.e. synchronized
    - Only way to find deadlocks in Java 5
  - **findDeadlockedThreads()**
    - Includes "monitor" and "owned" (Java 5) locks
    - Preferred method to test for deadlocks
    - But, does *not* find deadlocks between semaphores
  - See <http://www.javaspecialists.eu/archive/Issue130.html>

```
public class BankDeadlockTest {  
    private final static ThreadMXBean tmb =  
        ManagementFactory.getThreadMXBean();  
  
    private void checkThatThreadTerminates(Thread thread)  
        throws InterruptedException {  
        for (int i = 0; i < 2000; i++) {  
            thread.join(50);  
            if (!thread.isAlive()) return;  
            if (isThreadDeadlocked(thread.getId())) {  
                fail("Deadlock detected!");  
            }  
        }  
        fail(thread + " did not terminate in time");  
    }  
  
    private boolean isThreadDeadlocked(long tid) {  
        long[] ids = tmb.findDeadlockedThreads();  
        if (ids == null) return false;  
        for (long id : ids) {  
            if (id == tid) return true;  
        }  
        return false;  
    }  
}
```

```
@Test
public void testForTransferDeadlock()
    throws InterruptedException {
    final Account alpha = new Account(new DollarAmount(1000));
    final Account ubs = new Account(new DollarAmount(1000000));
    final Bank bank = new SlowBank(100, TimeUnit.MILLISECONDS);

    Thread alphaToUbs = new Thread("alphaToUbs") {
        public void run() {
            bank.transferMoney(alpha, ubs, new DollarAmount(100));
        }
    };
    Thread ubsToAlpha = new Thread("ubsToAlpha") {
        public void run() {
            bank.transferMoney(ubs, alpha, new DollarAmount(100));
        }
    };
    alphaToUbs.start();
    ubsToAlpha.start();

    checkThatThreadTerminates(alphaToUbs);
}
```

# Output With Broken TransferMoney() Method

- We see the deadlock within about 100 milliseconds

```
junit.framework.AssertionFailedError: Deadlock detected!
  at BankDeadlockTest.checkThatThreadTerminates(BankDeadlockTest.java:20)
  at BankDeadlockTest.testForTransferDeadlock(BankDeadlockTest.java:55)
```

- If we fix the transferMoney() method, it also completes within about 100 milliseconds
  - This is the time that we are sleeping for testing purposes
- Remember that the empty sleepAWhileForTesting() method will be optimized away by HotSpot

## Timed Lock Attempts

- Another technique for solving deadlocks is to use the timed `tryLock()` method of Java 5 locks (more in ch 13)
- Two things to consider
  - When a timed lock attempt fails, we do not necessarily know *why*
    - Could be deadlock
    - Could be another thread holding the lock whilst in an infinite loop
    - Could be some thread just taking a lot longer than expected
  - ThreadMXBean will show the thread as *deadlocked* whilst it is waiting for the lock

# Deadlock Analysis With Thread Dumps

- The **ThreadMXBean** can be invoked directly to find deadlocks between monitors or Java 5 locks
- However, we can also cause a thread dump in many ways:
  - Ctrl+Break on Windows or Ctrl-\ on Unix
  - Invoking "kill -3" on the process id
  - Calling jstack on the process id
    - Only shows deadlocks since Java 6
- Intrinsic locks typically show more information of where they were acquired than the explicit Java 5 locks

# Deadlock Analysis With Thread Dumps

- Thread dump from a real system (names changed)
- It is useful to have unique threads names
- The stack trace confirms the deadlock

Found one Java-level deadlock:

```
=====
"ApplicationServerThread-0":
    waiting to lock monitor 0x080f0cdc
        (object 0x650f7f30, a MumbleDBConnection),
    which is held by "ApplicationServerThread-1"
```

```
"ApplicationServerThread-1":
    waiting to lock monitor 0x080f0ed4
        (object 0x6024ffb0, a MumbleDBCallableStatement),
    which is held by "ApplicationServerThread-0"
```

## Stack Information Shows Where It Comes From

Java stack information for the threads listed above:

---

"ApplicationServerThread-0":

```
  at MumbleDBConnection.remove_statement
    - waiting to lock <0x650f7f30> (a MumbleDBConnection)
  at MumbleDBStatement.close
    - locked <0x6024ffb0> (a MumbleDBCallableStatement)
  ...
  ...
```

"ApplicationServerThread-1":

```
  at MumbleDBCallableStatement.sendBatch
    - waiting to lock <0x6024ffb0>
      (a MumbleDBCallableStatement)
  at MumbleDBConnection.commit
    - locked <0x650f7f30> (a MumbleDBConnection)
  ...
  ...
```

Found 1 deadlock.

## What Caused The Deadlock?

- Inside the JDBC driver, different calls acquired locks in different orders
  - JDBC vendor was trying to build a thread-safe driver
    - But then ended up writing a potential deadlock
  - This could be fixed in the JDBC driver by imposing a global order
- However, in the system the JDBC connection was shared by multiple threads
  - This caused the bug to appear
- Solution: single threaded access to each individual connection

## Stopping Deadlock Victims

- In extreme situations threads that are deadlocked in the WAITING state can be stopped as deadlock victims
- This only works with "owned" Java 5 locks, not monitors
  - A thread in the BLOCKED state cannot be stopped
- We can throw a special exception with Thread.stop()

```
public class DeadlockVictimError extends Error {  
    private final Thread victim;  
    public DeadlockVictimError(Thread victim) {  
        super("Deadlock victim: " + victim);  
        this.victim = victim;  
    }  
    public Thread getVictim() { return victim; }  
}
```

```
public class DeadlockArbitrator {  
    private static final ThreadMXBean tmb =  
        ManagementFactory.getThreadMXBean();  
  
    public boolean tryResolveDeadlock() throws InterruptedException {  
        return tryResolveDeadlock(3, 1, TimeUnit.SECONDS);  
    }  
  
    public boolean tryResolveDeadlock(  
        int attempts, long timeout, TimeUnit unit)  
        throws InterruptedException {  
        for (int i = 0; i < attempts; i++) {  
            long[] ids = tmb.findDeadlockedThreads();  
            if (ids == null) return true;  
            Thread t = findThread(ids[i % ids.length]);  
            if (t == null)  
                throw new IllegalStateException("Could not find thread");  
            t.stop(new DeadlockVictimError(t));  
            unit.sleep(timeout);  
        }  
        return false;  
    }  
  
    private Thread findThread(long id) {  
        for (Thread thread : Thread.getAllStackTraces().keySet()) {  
            if (thread.getId() == id) return thread;  
        }  
        return null;  
    }  
}
```

## Applicability Of DeadlockArbitrator

- **Only use in extreme circumstances**
  - Code that is outside your control and that deadlocks
  - Where you cannot prevent the deadlock
- **Remember, it only works with Java 5 locks (more later)**

## 10.3 Other Liveness Hazards

Avoiding Liveness Hazards

JavaSpecialists.eu  
java training

## 10.3 Other Liveness Hazards

- **Deadlock is the most common liveness hazard**
  - Even though there is no way to cleanly recover, it is usually fairly easy to recognize with the thread dumps
- **However, other liveness hazards can be more difficult to find, for example**
  - Starvation
  - Missed signals (covered in Chapter 14)
  - Livelock

## Threading Problems – Starvation

- In concurrent applications, a thread could perpetually be denied resources.
- Starvation can cause `OutOfMemoryError` or prevent a program from ever completing.

## Starvation In Java

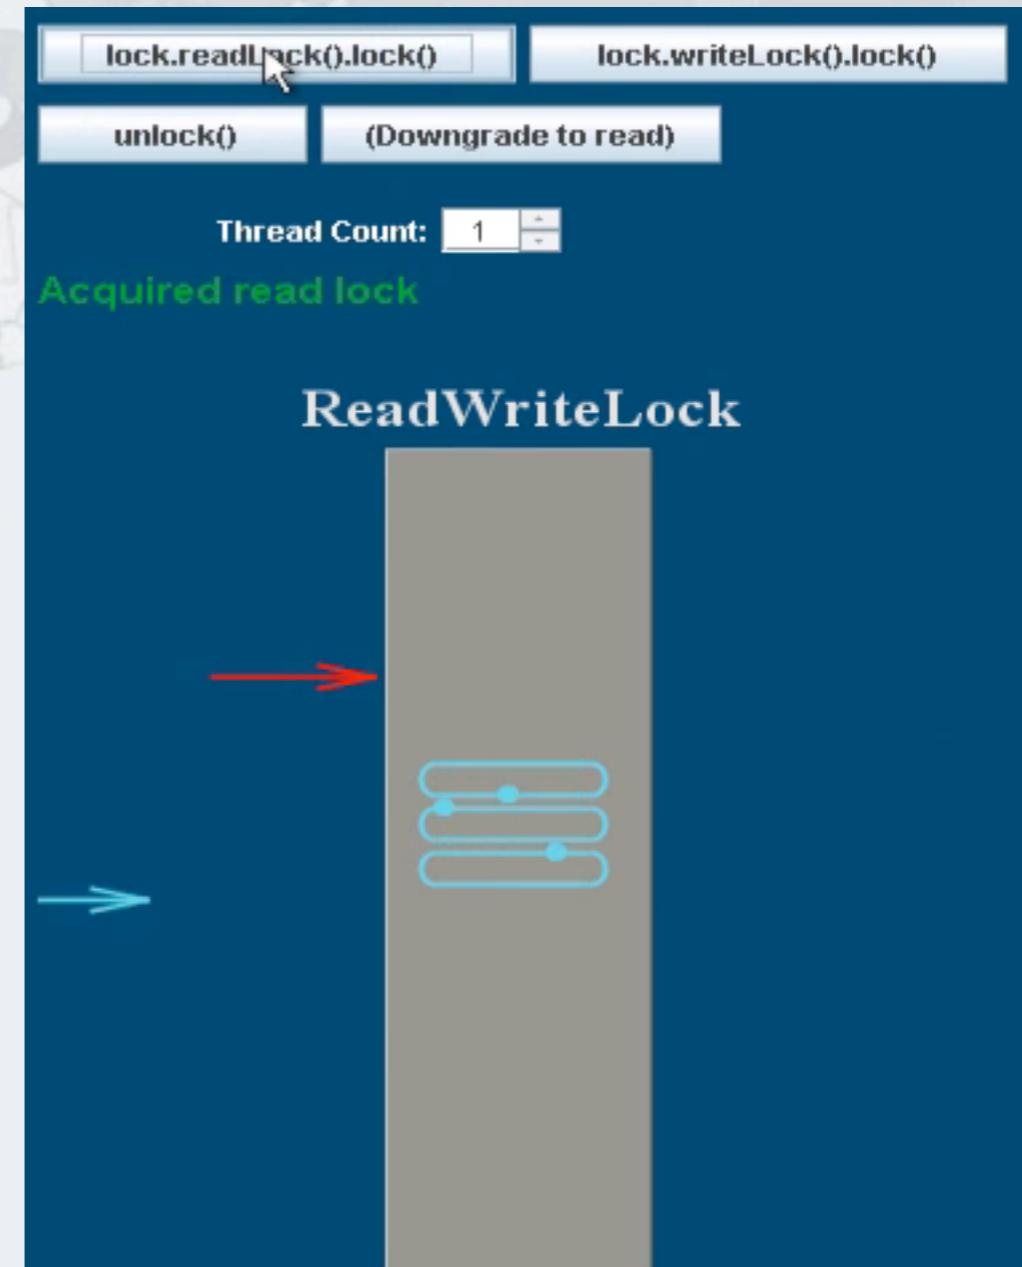

- Most common situation is when some low priority thread is ignored for long periods of time, preventing it from ever finishing work
- In Java, thread priorities are just a hint for the operating system. The mapping to system priorities is system dependent
- Tweaking thread priorities might result in starvation

## ReadWriteLock Starvation

- When readers are given priority, then writers might never be able to complete (Java 5)
- But when writers are given priority, readers might be starved (Java 6)
- Only use **ReadWriteLock** when you are sure that you will not continuously be acquiring locks
- See <http://www.javaspecialists.eu/archive/Issue165.html>

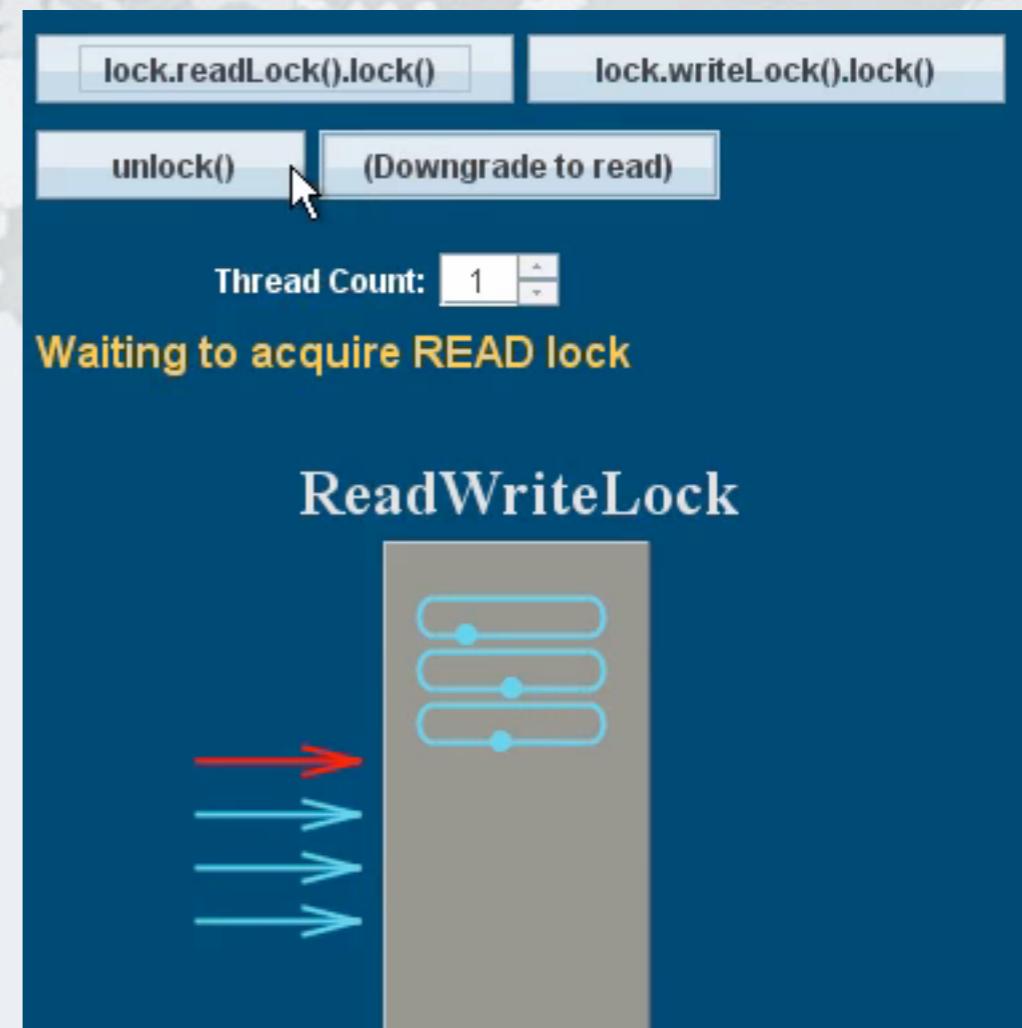

# Java 5 ReadWriteLock Starvation

- We first acquire some read locks
- We then acquire one write lock
- Despite write lock waiting, read locks are still issued
- If enough read locks are issued, write lock will never get a chance and the thread will be starved!

## ReadWriteLock In Java 6

- Java 6 changed the policy and now read locks have to wait until the write lock has been issued
- However, now the readers can be starved if we have a lot of writers

## Livelock

- Thread is running, but still not making progress
- Typically forever retrying a failed operation
  - Eventually you need to give up
- Often occurs in transactional messaging applications, where the messaging infrastructure rolls back a transaction if a message cannot be processed successfully, and puts it back at the head of the queue.
  - This form of livelock often comes from overeager error-recovery code that mistakenly treats an unrecoverable error as a recoverable one.

## Real-World Scenario

- Two polite people meet in a narrow corridor. Each steps to the side to make room for the other. They keep on doing this at the same time, never getting past each other.
  - Fortunately people are not that stupid
    - But computers are!
- Can happen especially in code that tries to recover from a deadlock situation
  - Only possible with Java 5 locks, in a controlled fashion

# Livelock In IntelliJ IDEA

The screenshot shows the IntelliJ IDEA interface with the following details:

- Title Bar:** WildFactorizer.java - [Concurrency] - [~/svn/courses/concurrency/samples/Concurrency] - IntelliJ IDEA (Nika) IU-111.255
- Toolbar:** Standard IntelliJ toolbar with icons for file operations, search, and navigation.
- Project Structure:** Shows the project structure under the "Concurrency" package, including sub-directories like "src" and various chapters ("ch01\_introduction", "ch02\_thread\_safety", etc.) and their corresponding exercise and solution files.
- Code Editor:** The main editor window displays the `WildFactorizer.java` code. The class definition is highlighted with a yellow background. The code uses `AtomicLong` and `Factorizer` from the `concurrency.math.*` package.
- Tool Window:** A vertical tool window on the right side contains the text "10.3 Other Liveness Hazards".
- Status Bar:** At the bottom, it shows "Compilation aborted (moments ago)" and system information like time (7:20), encoding (UTF-8), and memory usage (171M of 2043M).

## 10.4: Where To From Here?

## The Java Specialists' Newsletter

- Written for programmers who use Java professionally
- Please subscribe for free here:
  - <http://www.javaspecialists.eu/archive/subscribe.jsp>

# Advanced Java Training With ExitCertified

- **Concurrency Specialist Course**
  - More of what we did today, also looking at safety, Fork/Join, etc.
- **Java Specialist Master Course**
  - Threading, Java NIO, reflection, data structures, performance
- **Design Patterns Course**
  - The most useful Gang-of-Four patterns, in Java

# 10: Exercises

## Avoiding Liveness Hazards

JavaSpecialists.eu  
java training

## Exercise 10.1: Test Java2Demo For Liveness

- Run the Java2Demo and check for liveness, such as
  - Deadlock
    - You would notice that part of the program stops responding
  - Livelock
    - Typically your CPU is very high, without any real progress made
- Please download the workshop exercises from:
  - <http://tinyurl.com/conc-zip>
- Workshop support information is available here:
  - <http://javaspecialists.eu/courses/concurrency/exitcertified.jsp>
